## PRZEDMOWA

Niniejszy, LXXVI tom Rocznika Astronomicznego jest kontynuacją serii roczników astronomicznych opracowywanych i wydawanych nakładem Instytutu Geodezji i Kartografii w Warszawie od 1946 roku. Został on opracowany w ramach realizacji zadań statutowych Centrum Geodezji i Geodynamiki IGiK. Zespół autorski LXXVI tomu Rocznika Astronomicznego stanowią: Jan Kryński i Marcin Sękowski.

Podobnie jak w latach 2002–2020 Rocznik Astronomiczny na rok 2021 obok wersji drukowanej został opracowany także w formie elektronicznej, w formacie *pdf*. Począwszy od Rocznika na 2015 rok obie wersje są jednak różne. Wersja elektroniczna pozostała w swojej strukturze niezmieniona natomiast wersja drukowana Rocznika jest istotnie skrócona w stosunku do wersji elektronicznej; ze względów edytorskich zmieniono w niej również układ tablic. Obie wersje Rocznika uzupełnia **Rocznik Astronomiczny „on–line”**.

Wprowadzone zmiany mają swe źródło, przede wszystkim, w dążeniu do zapewnienia największej możliwej spójności pomiędzy dokładnościami danych zawartych w Roczniku a ich możliwym do osiągnięcia poziomem, wynikającym z dokładności danych źródłowych oraz stosowanych współcześnie modeli obliczeniowych. Dotyczy to przede wszystkim pozycji pozornych gwiazd w Niebieskim Systemie Pośrednim (*IRS*) obliczanych przy wykorzystaniu tablic miejsc pozornych gwiazd w tym systemie. Dokładność wartości interpolowanych wewnątrz przedziału danych podawanych w tablicach przy przyjętym dla większości gwiazd 7-dniowym kroku tablicowania pozostawała na poziomie znacząco niższym od wartości możliwych do osiągnięcia na drodze bezpośrednich obliczeń na zadany moment. Naturalnym rozwiązaniem tego problemu była więc rezygnacja z dotychczasowego sposobu tabelarycznej prezentacji części danych w wersji drukowanej Rocznika i przeniesienie ich do Internetu — Rocznika Astronomicznego „on–line”.

W wersji drukowanej Rocznika, począwszy od wydania na 2015 rok, usunięto tablice miejsc pozornych gwiazd w systemie *IRS*, tablice miejsc pozornych gwiazd okołobiegunowych w systemie *IRS*, tablice pozycji gwiazd w systemie *ICRS* oraz tablice barycentrycznych i heliocentrycznych pozycji Ziemi, natomiast, począwszy od wydania na 2017 rok usunięto dodatkowo tablice miejsc średnich gwiazd FK5, tablice wielkości redukcyjnych, tablice miejsc pozornych gwiazd w systemie FK5 oraz tablice miejsc pozornych gwiazd okołobiegunowych w systemie FK5. Usunięte tablice zastąpił **kalkulator pozycji pozorowanej gwiazdy** zapewniający możliwość bezpośredniego obliczenia pozycji pozorowanej wybranej gwiazdy na dowolny zadany moment w Roczniku Astronomicznym „on–line”.

Zarówno wersja elektroniczna Rocznika (*pdf*), jak i Rocznik Astronomiczny „on–line” (kalkulator pozycji pozorowanej) są dostępne na stronach internetowych Centrum Geodezji i Geodynamiki IGiK (<http://www.igik.edu.pl>).

W kolejnych wydaniach Rocznika, począwszy od wydania na 2004 rok, uwzględniono zmiany definicji niebieskich systemów odniesienia, transformacji między tymi systemami oraz systemów czasu, dostosowujące je do precyzji współczesnych technik obserwacyjnych (poniżej mikrosekundy łuku). Zmiany te, przyjęte przez Międzynarodową Unię Astronomiczną (IAU) w 2000 r. oraz przez Międzynarodową Unię Geodezji i Geofizyki (IUGG) w 2003 r. obowiązują od 1 stycznia 2003 roku. Stosując się do zaleceń IAU i IUGG wprowadzono również dalsze zmiany wynikające z rezolucji kolejnych Zgromadzeń Generalnych IAU (Praga, 2006; Rio de Janeiro, 2009; Pekin, 2012; Honolulu, 2015; Wiedeń, 2018) i IUGG (Perugia, 2007; Melbourne, 2011; Montreal, 2019).

Zawarte w tablicach Rocznika na 2021 rok pozycje Słońca i Księżyca oraz pozycje gwiazd są wyrażone, zgodnie z zaleceniami IAU, zarówno w nowym Niebieskim Pośrednim Systemie Odniesienia o początku *CIO*, jak i w ujęciu „klasycznym” związanym z punktem równonocy wiosennej.

W pracach nad Rocznikiem Astronomicznym na 2021 rok korzystano z materiałów z kolejnych Zgromadzeń Generalnych IAU i IUGG, zbiorów opracowań: IERS Technical Note 29 (zawierającą publikacje z Workshopu IERS „Implementation of the New IAU Resolutions”), który się odbył w kwietniu 2002 roku w Paryżu, „IERS Conventions 1996”, „IERS Conventions 2003”, „IERS Conventions 2010”, opracowań Grup Roboczych Oddziału Astronomii Fundamentalnej IAU i szeregu publikacji, zaczerpniętych głównie z Astronomy & Astrophysics, a także z materiałów Workshopu Sekcji Dynamiki Ziemi Komitetu Geodezji PAN w Warszawie w maju 2004 roku.

Zawartość większości tablic w Roczniku stanowi wynik obliczeń wykonanych w Centrum Geodezji i Geodynamiki IGiK przy użyciu programów własnych, w których zostały wykorzystane procedury udostępnione przez IERS i SOFA — wszystkich opracowanych przez Marcina Sękowskiego. Do sporządzenia efemeryd Słońca, Księżyca i planet Układu Słonecznego posłużyły dane efemerydalne DE405/LE405.

Dane liczbowe dotyczące zaćmień Słońca i Księżyca zostały zaczerpnięte ze stron „NASA Eclipse Web Site”. Współrzędne bieguna północnego Ziemi *CIP* oraz różnice *UT1 – UTC* zaczerpnięto z wydawnictw Centralnego Biura Międzynarodowej Służby Ruchu Obrotowego Ziemi (IERS) w Paryżu. Program do interpolacji izogon deklinacji magnetycznej oraz mapę tych deklinacji na rok 2021 sporządziła Elżbieta Welker. Informacje o radiowych sygnałach czasu oparte są na corocznie uaktualnianych danych dostarczanych przez Bureau International des Poids et Mesures w Sèvres. Programy używane do tablicowania danych i formatowania Rocznika oraz skład całości Rocznika w systemie  $\text{\TeX}$ , zarówno drukowanej wersji książkowej, jak i elektronicznej *pdf* zostały wykonane przez Marcina Sękowskiego. Obliczenia kontrolne przykładów numerycznych zamieszczonych w części szczegółowej Rocznika wykonali Marcin Sękowski i Kamila Karkowska.

Definicje i wielkości stałych astronomicznych użyte w Roczniku odnoszą się do systemu IAU2009. Zostały one zaczerpnięte ze strony (<http://maia.usno.navy.mil/NSFA/CBE.html>). Dołączono również uzupełniającą listę stałych i wielkości pomocniczych — niektóre odniesione do poprzednio obowiązujących systemów, które mogą być stosowane w obliczeniach nie wymagających najwyższych dokładności, a także zalecane przez Zgromadzenie Generalne IAU (Honolulu, 2015) nominalne stałe konwersji dla wybranych własności słonecznych i planetarnych.

Algorytmy i programy opracowane do obliczania podanych w niniejszym Roczniku pozycji ciał niebieskich, wyrażonych w nowych systemach odniesienia, były poddane skrupulatnej kontroli wewnętrznej i weryfikacji. Ich poprawność została także potwierdzona zgodnością publikowanych danych z danymi zawartymi w innych wydawnictwach rocznikowych, w których wdrażane są na bieżąco zalecenia IAU (Apparent Places of Fundamental Stars, Astronomisches Rechen-Institut, Heidelberg; Astronomičeskij Jeżegodnik, Institut Prikladnoj Astronomii RAN, St. Petersburg; The Astronomical Almanac, Waszyngton/Londyn).

$\tau$  odstęp czasu między górowaniem a wschodem lub zachodem a górowaniem Księżyca.

Znaki tablic odnoszą się do wschodu. Dla zachodu należy zmienić znaki na przeciwne.

Uwaga: oprócz poprawki z tej tablicy, należy odjąć różnicę długości geograficznej  $\lambda_i - \lambda_{W-wa}$ .

Tabela zawiera wszystkie koniunkcje, w których odległość kątowa ciał niebieskich nie przekracza 4°.1.

## Zaćmienia Słońca, Księżyca w 2021 roku

### 1. Całkowite zaćmienie Księżyca 26 maja 2021 roku.

Początek zaćmienia będzie widoczny na zachodnim wybrzeżu Australii, archipelagu wysp Sundajskich, wschodnim wybrzeżu Azji: w Japonii, Chinach, Indochinach oraz w Indiach i we wschodniej części Oceanu Indyjskiego.

Koniec zaćmienia będzie widoczny w zachodniej części Oceanu Atlantyckiego, na obszarze obu Ameryk i na wschodnich krańcach Oceanu Spokojnego.

Moment opozycji Słońca i Księżyca w rektascensji: 2021 maj 26<sup>d</sup> 11<sup>h</sup>13<sup>m</sup>50<sup>s</sup>.1 UT.

| Fazy zaćmienia                 | UT  |
|--------------------------------|---|
| Wejście Księżyca w półcień     | maj 26 <sup>d</sup> 8 <sup>h</sup> 47 <sup>m</sup> 7 <sup>s</sup> |
| Początek częściowego zaćmienia | 9 45.0  |
| Początek całkowitego zaćmienia | 11 11.4   |
| Moment największej fazy        | 11 18.7   |
| Koniec całkowitego zaćmienia   | 11 25.9   |
| Koniec częściowego zaćmienia   | 12 52.4   |
| Wyjście Księżyca z półcienia   | 13 49.7   |

Kątowy promień półcienia = 4673<sup>''</sup>.16, kątowy promień cienia = 2778<sup>''</sup>.84.

Wielkość największej fazy zaćmienia = 1.0095 średnicy tarczy Księżyca.

Równikowa horyzontalna paralaksa Słońca = 8<sup>''</sup>.7, Księżyca = 61' 20<sup>''</sup>.5 w momencie opozycji.

Kątowy geocentryczny promień tarczy Słońca = 15' 47<sup>''</sup>.3, Księżyca = 16' 42<sup>''</sup>.9 w momencie opozycji.

### 2. Obrączkowe zaćmienie Słońca 10 czerwca 2021 roku.

Zaćmienie będzie widoczne w północnej Kanadzie, na Grenlandii, biegunie północnym, Oceanie Arktycznym oraz na Alasce.

Moment koniunkcji Słońca i Księżyca w rektascensji: 2021 czerwiec 10<sup>d</sup> 11<sup>h</sup>00<sup>m</sup>58<sup>s</sup>.7 UT.

| Fazy zaćmienia                 | UT                 | Szer. geogr. | Dług. geogr. |
|--------------------------------|--------------------|--------------|--------------|
| Początek częściowego zaćmienia | czerwiec 10 8 12.3 |              |              |
| Początek centralnego zaćmienia | 9 49.7             |              |              |
| Moment największego zaćmienia  | 10 41.9            | 80° 48' 9" N | 66° 48' 3" W |
| Koniec centralnego zaćmienia   | 11 33.7            |              |              |
| Koniec częściowego zaćmienia   | 13 11.3            |              |              |

Równikowa horyzontalna paralaksa Słońca = 8<sup>''</sup>.7, Księżyca = 54' 14<sup>''</sup>.4 w momencie koniunkcji.

Kątowy geocentryczny promień tarczy Słońca = 15' 45<sup>''</sup>.2, Księżyca = 14' 46<sup>''</sup>.8 w momencie koniunkcji.

### 3. Częściowe zaćmienie Księżyca 19 listopada 2021 roku.

Początek zaćmienia będzie widoczny w zachodniej części Oceanu Spokojnego, w Australii, wschodniej i centralnej części Azji i na Oceanie Arktycznym.

Koniec zaćmienia będzie widoczny na Oceanie Arktycznym, północnej i zachodniej Europie, na zachodnich krańcach Afryki, północno-zachodniej części Oceanu Atlantyckiego, w Ameryce Południowej i południowo-wschodnich krańcach Pacyfiku.

Moment opozycji Słońca i Księżyca w rektascensji: 2021 listopad 19<sup>d</sup> 8<sup>h</sup>57<sup>m</sup>24<sup>s</sup>.4 UT.

| Fazy zaćmienia                 | UT   |
|--------------------------------|--|
| Wejście Księżyca w półcień     | listopad 19 <sup>d</sup> 6 <sup>h</sup> 02 <sup>m</sup> 2 <sup>s</sup> |
| Początek częściowego zaćmienia | 7 18.7   |
| Moment największej fazy        | 9 02.9   |
| Koniec częściowego zaćmienia   | 10 47.1  |
| Wyjście Księżyca z półcienia   | 12 03.6  |

Kątowy promień półcienia = 4258<sup>''</sup>.44, kątowy promień cienia = 2316<sup>''</sup>.24.

Wielkość największej fazy zaćmienia = 0.9742 średnicy tarczy Księżyca.

Równikowa horyzontalna paralaksa Słońca = 8<sup>''</sup>.9, Księżyca = 54' 06<sup>''</sup>.1 w momencie opozycji.

Kątowy geocentryczny promień tarczy Słońca = 16' 11<sup>''</sup>.0, Księżyca = 14' 44<sup>''</sup>.5 w momencie opozycji.

#### 4. Całkowite zaćmienie Słońca 4 grudnia 2021 roku.

Zaćmienie widoczne będzie na południowym krańcu Oceanu Spokojnego, na Antarktydzie i południowo-zachodnim krańcu Oceanu Atlantyckiego.

Moment koniunkcji Słońca i Księżycy w rektascensji: 2021 grudzień 4<sup>d</sup> 7<sup>h</sup>56<sup>m</sup>04<sup>s</sup>.9 UT.

| Fazy zaćmienia                 |            | UT        | Szer. geogr. | Dług. geogr. |
|--------------------------------|------------|-----------|--------------|--------------|
| Początek częściowego zaćmienia | grudzień 4 | 5 29 11.3 |              |              |
| Początek całkowitego zaćmienia |            | 7 00 01.0 |              |              |
| Moment największego zaćmienia  |            | 7 33 22.5 | 76° 46'7 S   | 46° 11'9 W   |
| Koniec całkowitego zaćmienia   |            | 8 06 29.2 |              |              |
| Koniec częściowego zaćmienia   |            | 9 37 23.9 |              |              |

Równikowa horyzontalna paralaksa Słońca = 8", Księżycy = 61' 27".3 w momencie koniunkcji.

Kątowy geocentryczny promień tarczy Słońca = 16' 13".6, Księżycy = 16' 44".7 w momencie koniunkcji.

Dane stanowią wynik obliczeń prowadzonych na bieżąco przez IERS, aktualizowanych dwa razy w tygodniu i publikowanych jako tzw. rozwiązanie C04. Tablica zawiera dane dostępne w chwili wydawania Rocznika.

Dane są na bieżąco dostępne na serwerze IERS pod adresem: <ftp://ftp.iers.org/products/eop/long-term/>.

Przewidywane współrzędne bieguna *CIP* („chwilowego” bieguna północnego Ziemi) w odniesieniu do *IRP* oraz poprawka do czasu uniwersalnego,  $0^h$  *UTC*

Tablica zawiera wartości przewidywane, publikowane przez IERS Rapid Service/Prediction Center w USNO, w wydawanych co kilka dni tzw. biuletynach A. Tablica przedstawia wartości opracowane w oparciu o dane dostępne w chwili wydawania Rocznika.

Bieżące przewidywane współrzędne bieguna i poprawki do czasu uniwersalnego są dostępne pod adresem: <ftp://maia.usno.navy.mil/ser7/ser7.dat> lub <ftp://cddis.gsfc.nasa.gov/pub/products/iers/ser7.dat>.

Opracowano na podstawie: *BIPM Annual Report on Time Activities, Vol. 13, 2018.*

## MAPA DEKLINACJI MAGNETYCZNEJ NA EPOKĘ 2021.5

Izogony poprowadzono co 30'

Zmiana roczna wynosi 8'

*Przykład obliczania wartości deklinacji magnetycznej.*

Dla punktu o współrzędnych  $\varphi = 23^{\circ}00'$  i  $\lambda = 51^{\circ}00'$   
wartość deklinacji wschodniej na epokę 2021.5 wynosi

$$D_{2021.5} \approx 6^{\circ}26'$$

Obliczenie wartości deklinacji magnetycznej na epokę 2021.9

$$D_{2021.9} = D_{2021.5} + (\text{zmiana roczna} \times (2021.9 - 2021.5))$$

$$D_{2021.9} \approx 6^{\circ}29'$$

Gwiazdozbiory Carina, Puppis, Pyxis i Vela poprzednio tworzyły jeden gwiazdozbiór Argo navis (Okręt Argo).

Gwiazdozbiór Serpens bywa dzielony na: Serpens caput (Głowa Węża) i Serpens cauda (Ogon Węża). Numeracja gwiazd jest jednolita w łącznym gwiazdozbiore.

Wcześniejsze podziały na gwiazdozbiory były najpierw związane tylko z ugrupowaniami jaśniejszych gwiazd, następnie z obszarami nieba dość nieregularnymi bez wyraźnie sprecyzowanych granic.

## NIEKTÓRE STAŁE, DEFINICJE I WZORY ASTRONOMICZNE I GEODEZYJNE

System stałych astronomicznych i geodezyjnych oraz niektóre wzory podawane w kolejnych tomach Rocznika Astronomicznego (RA) oparte były na uchwałach podejmowanych przez Zgromadzenia Generalne (ZG) Międzynarodowej Unii Astronomicznej (IAU) i Międzynarodowej Unii Geodezji i Geofizyki (IUGG). Uchwały były zazwyczaj przygotowywane przez grupy robocze odpowiednich komisji tych unii, których zadaniem było opracowanie spójnego systemu stałych, najbardziej zbliżających teorię ruchu Ziemi i ciał niebieskich do wyników obserwacji astronomicznych. Rozwój metod i technik pozyskiwania danych wymuszał bowiem udoskonalanie teorii i rewizję poszczególnych stałych systemu. Wyrazem tego były stopniowo wprowadzane zmiany na mocy uchwał ZG IAU (Hamburg, 1964; Praga, 1967) oraz IUGG (Lucerna, 1967; Grenoble, 1975). Uchwałą XVI ZG IAU w Grenoble (1976) ustanowiono nowy, spójny i odpowiadający współcześnie używanym dokładnościom „System Stałych Astronomicznych IAU1976”. Kilka lat później, XVII ZG IUGG (Canberra, 1979) ustanowiło jako oficjalny „Geodezyjny System Odniesienia 1980” (GRS80). Na mocy kolejnych uchwał ZG IAU (Montreal, 1979; Patras, 1982) wprowadzono szereg poprawek i ustalono, że tak powstały system (stałe astronomiczne i model precesji IAU1976 oraz teoria nutacji IAU1980) ma obowiązywać w pracach astronomicznych począwszy od 1984 r.

W konfrontacji z osiągnięciami nowych technik obserwacyjnych system stałych astronomicznych IAU1976 wkrótce okazał się niedostatecznie dokładny i w 1991 roku ZG IAU w Buenos Aires ustanowiło nowy system, który na następnym ZG IAU (Haga, 1994) został zarekomendowany do powszechnego stosowania w obliczeniach astronomicznych<sup>1)</sup>. Na tym samym Zgromadzeniu Generalnym, stwierdzając potrzebę poprawienia stałych nutacji i precesji, polecono Międzynarodowej Służbie Ruchu Obrotowego Ziemi (IERS) opracowanie w trybie pilnym modelu nutacji i precesji na okres przejściowy, lepiej pasującego do obserwacji uzyskiwanych technikami VLBI i LLR.

Powołane na wspomnianych wyżej Zgromadzeniach Generalnych grupy robocze do spraw stałych fundamentalnych, układów odniesienia i ruchu obrotowego Ziemi, w tym działające również na płaszczyźnie międzyunijnej (IAU i IUGG), w porozumieniu z IERS i zgodne z zaleceniami XXIII ZG IAU (Kyoto, 1997), kontynuowały prace nad poprawieniem spójności systemu stałych astronomicznych, definicją jednostek, wartościami stałych podstawowych i stałych pochodnych oraz ujednoliceniem stosowanych algorytmów. Wyniki tych prac, ukierunkowane na:

- utrzymywanie w stanie aktualności Międzynarodowego Niebieskiego Systemu Odniesienia *ICRS* w powiązaniu z układem odniesienia katalogu Hipparcos, jako podstawowej realizacji *ICRS* dla astrometrii optycznej,
  - powiązanie układu odniesienia Systemu Słonecznego z systemem *ICRS*,
  - śledzenie stanu oceanu światowego i rozszerzenie badań nad atmosferą, tak aby ich wpływ na nieregularność obrotu Ziemi mógł być modelowany poprawnie niż obecnie,
  - śledzenie zmian położenia środka ciężkości Ziemi,
  - poprawienie spójności wewnętrznej parametrów orientacji Ziemi oraz układów odniesienia ziemskiego i niebieskiego,
- były przedmiotem obrad ZG IUGG (Birmingham, 1999) i IAU (Manchester, 2000). Na XXIII ZG IAU (Kyoto, 1997) przyjęto nową obowiązującą definicję Międzynarodowego Niebieskiego Układu Odniesienia (*ICRF*).

XXIV ZG IAU (Manchester, 2000) uściśliło definicje systemów odniesienia, Czasu Ziemskiego (*TT*), a także określenia wzajemnych relacji pomiędzy systemami. Zaleciło ono zastąpienie od 1 stycznia 2003 r. modelu precesji IAU1976 oraz teorii nutacji IAU1980 nowym modelem precesyjno–nutacyjnym IAU2000A<sup>2)</sup>. Ustalenia te zostały zaaprobowane przez XXIII ZG IUGG w Sapporo w 2003 r. Wprowadzenie nowego modelu precesyjno–nutacyjnego wiązało się z nowymi, spójnymi z nim, definicjami Pośredniego Bieguna Niebieskiego (*CIP*), który zastąpił Efemerydalny Biegun Niebieski (*CEP*) oraz definicjami Niebieskiego Efemerydalnego Punktu Początkowego (*CEO*) i Ziemskiego Efemerydalnego Punktu Początkowego (*TEO*) — przemianowanymi przez XXVI ZG IAU (Praga, 2006) odpowiednio na Niebieski Pośredni Punkt Początkowy (*CIO*) i Ziemski Pośredni Punkt Początkowy (*TIO*). Na tym samym zgromadzeniu przyjęto rezolucje ustalające orientacje osi *BCRS* i *GCRS*, uściślające definicję *TDB* oraz wprowadzające nowy model precesji P03, który od 1 stycznia 2009 r. zastąpił część precesyjną modelu precesyjno–nutacyjnego IAU2000. XXIV ZG IUGG (Perugia, 2007) zaaprobowало ustalenia ZG IAU z Pragi i dodatkowo wprowadziło Geocentryczny Ziemski System Odniesienia *GTRS*, który został zdefiniowany w zgodności z Rezolucją B1.3 ZG IAU w 2000 r. oraz uzupełniło definicję Międzynarodowego Ziemskiego Systemu Odniesienia *ITRS* jako szczególnego Geocentrycznego Ziemskiego Systemu Odniesienia *GTRS*, którego orientacja jest operacyjnie utrzymywana w ciągłości z poprzednimi uzgodnieniami międzynarodowymi (orientacja BIH). Na mocy Rezolucji B3 XXVII ZG IAU w Rio de Janeiro w 2009 r. druga realizacja Międzynarodowego Niebieskiego Układu Odniesienia *ICRF2* zastąpiła od 1 stycznia 2010 r. *ICRF* jako fundamentalna astrometryczna realizacja *ICRS*. To samo zgromadzenie w Rezolucji B2 określiło nowe stałe astronomiczne IAU2009 oraz strategię ich uaktualniania. W 2011 roku *ICRF2* został również przyjęty przez XXV ZG IUGG (Melbourne, Rezolucja 3). Na mocy Rezolucji B2 XXVIII ZG IAU (Pekin, 2012) wprowadzono nową definicję długości jednostki astronomicznej nadając jej oznaczenie *au*. Jednostkę astronomiczną uznano za pomocniczą stałą definiującą natomiast stałą grawitacyjną Gaussa *k* usunięto ze stałych astronomicznych.

<sup>1)</sup> Szczegółowy opis tego systemu, zmiany definicji oraz wartości numerycznych stałych astronomicznych zostały przedstawione na stronach 136 ÷ 144 Rocznika Astronomicznego na 1992 rok.

<sup>2)</sup> Dokładny opis ustaleń XXIV ZG IAU przedstawiono na stronach 214 ÷ 221 Rocznika Astronomicznego na 2004 rok.

XXIX ZG IAU (Honolulu, 2015) zaleciło w Rezolucji B3 stosowanie nominalnych stałych konwersji dla wybranych własności słonecznych i planetarnych. Na kolejnym XXX ZG IAU (Wiedeń, 2018) podjęto istotne decyzje w sprawie definicji i realizacji ziemskiego i niebieskiego układu odniesienia. W Rezolucji B1 zalecono przyjęcie *ITRS* jako preferowanego *GTRS* w zastosowaniach naukowych i technicznych. W Rezolucji B2 przyjęto zaś trzecią realizację Międzynarodowego Niebieskiego Systemu Odniesienia *ICRF3*, która obowiązuje od 1 stycznia 2019 roku.

Ośrodki zrzeszone w uniach IAU i IUGG są także zachęcane do prowadzenia badań pionowych i poziomych ruchów skorupy ziemskiej, do prac nad łącznym opracowywaniem obserwacji uzyskiwanych za pomocą różnych technik pomiarowych i do ściślejszej współpracy z grupami roboczymi tych unii. Do upowszechniania przyjętych standardów (konwencji) zobowiązano IERS<sup>3)</sup>.

### Zasadnicze różnice w definicjach systemów odniesienia

| Systemy używane do 1991 roku   | Systemy obowiązujące od 2003 roku   |
|--|---|
| <b>1. Ogólne</b>   |   |
| podstawy teoretyczne: <b>mechanika newtonowska</b> (z poprawkami relatywistycznymi)  | podstawy teoretyczne: <b>mechanika relatywistyczna</b>  |
| zapewnienie dokładności na poziomie <b>milisekundy</b> łuku ( <i>mas</i> )   | zapewnienie dokładności na poziomie <b>mikrosekundy</b> łuku ( <i>μas</i> )   |
| <b>2. Systemy niebieskie</b>   |   |
| system odniesienia: <b>FK5</b>   | system odniesienia: <b>ICRS</b> <ul style="list-style-type: none"> <li>– <b>BCRS</b> — dla Układu Słonecznego</li> <li>– <b>GCRS</b> — dla powiązania z ziemskim systemem odniesienia i monitorowania EOP</li> </ul>  |
| <b>FK5</b> — <b>dynamiczny</b> układ odniesienia (określony na podstawie rozwiązania planetarnych równań ruchu i zdefiniowany poprzez pozycje jasnych gwiazd)  | <b>ICRF</b> — <b>kinematyczny</b> układ odniesienia (zdefiniowany poprzez pozycje obiektów pozagalaktycznych)   |
| <b>FK5</b> — <b>nieustalone</b> położenie względem układu inercjalnego — określane na epokę katalogu.  | <b>ICRF</b> — <b>kinematycznie ustalone</b> położenie względem układu inercjalnego (ruchy własne obiektów pozagalaktycznych — uznane za zanedbywalnie małe)   |
| kierunki osi odniesione do określonych na epokę: <b>bieguna FK5</b> (definiującego płaszczyznę równika) i kierunku <b>równonocy wiosennej</b> (wyznaczonego przez przecięcie płaszczyzn równika i ekliptyki)   | kierunki osi odniesione do ustalonych: <b>bieguna ICRF</b> (niemal pokrywający się z <b>CEP</b> FK5 na epokę J2000.0) i <b>początku liczenia rektascensji w ICRS</b> (niemal pokrywający się z kierunkiem równonocy wiosennej FK5 na epokę J2000.0)                       |
| <b>3. System pośredni</b>  |   |
| kierunki osi pośredniego systemu niebieskiego odniesione do <b>CEP</b> (definiującego płaszczyznę <b>prawdziwego równika</b> ) i kierunku <b>równonocy wiosennej</b> (wyznaczonego przez przecięcie płaszczyzn <b>prawdziwego równika</b> i <b>ekliptyki</b> ) | kierunki osi pośredniego systemu niebieskiego określone przez <b>CIP</b> (niemal pokrywający się z <b>CEP</b> FK5 na epokę J2000.0) i <b>CIO</b> (niemal pokrywający się z kierunkiem równonocy wiosennej FK5 na epokę J2000.0) — w latach 2003–2006 pod nazwą <b>CEO</b> |
| kierunek osi <i>x</i> pośredniego systemu ziemskiego określony przez przecięcie płaszczyzny <b>chwilowego południka Greenwich</b> z <b>równikiem CEP</b>   | kierunek osi <i>x</i> pośredniego systemu ziemskiego określony przez <b>TIO</b> (przecięcie chwilowego południka zerowego <i>ITRS</i> z <b>równikiem CIP</b> ) — w latach 2003–2006 pod nazwą <b>TEO</b>  |
| relacja pomiędzy niebieskim i ziemskim pośrednim systemem odniesienia wyrażona w funkcji <b>prawdziwego czasu gwiazdowego Greenwich (GST)</b>  | relacja pomiędzy niebieskim i ziemskim pośrednim systemem odniesienia wyrażona w funkcji <b>Kąta Obrotu Ziemi (ERA)</b>   |
| <b>4. System ziemski</b>   |   |
| kierunki osi systemu <i>CTS</i> określone przez <b>CIO*</b> i <b>zerowy południk BIH</b>   | kierunki osi systemu <i>ITRS</i> określone przez <b>biegun IERS ITRS</b> oraz <b>zerowy południk ITRS</b>   |

<sup>3)</sup> Dane szczegółowe na temat ewolucji systemu stałych astronomicznych można uzyskać m.in. na stronach internetowych IAU (<http://www.iau.org>) oraz IERS (<http://www.iers.org>).

## Jednostki astronomiczne

- Jednostkami długości, masy i czasu są jednostki międzynarodowego systemu jednostek (SI), mianowicie: metr ( $m$ ), kilogram ( $kg$ ) i sekunda ( $s$ ).
- Astronomiczną jednostką czasu jest doba ( $d$ ). Jest to interwał czasu wynoszący 86 400 sekund SI. Przez stulecie juliańskie ( $JC$  — Julian Century) jest rozumiany interwał czasu wynoszący 36 525 dób.
- Astronomiczną jednostką masy jest masa Słońca ( $M_S$ ).
- Astronomiczną jednostką długości, opartą na średniej odległości Ziemia—Słońce, jest długość ( $au$ ) wynosząca dokładnie 149 597 870 700  $m$ .

## System stałych astronomicznych IAU2009

### Stałe definiujące

#### Naturalne stałe definiujące

Prędkość światła w próżni  $c = 299\,792\,458\,ms^{-1}$

#### Pomocnicze stałe definiujące

|   |   |
|---|---|
| Współczynnik zmiany skali czasu od $TT$ do $TCG$  | $L_G = 6.969\,290\,134 \times 10^{-10}$   |
| Współczynnik zmiany skali czasu od $TCB$ do $TDB$ | $L_B = 1.550\,519\,768 \times 10^{-8}$  |
| Stała początkowa przy przejściu od $TCB$ do $TDB$ | $TDB_0 = -6.55 \times 10^{-5}\,s$   |
| Astronomiczna jednostka długości                  | $au = 1.495\,978\,707\,00 \times 10^{11}\,m$  |
| Kąt Obrotu Ziemi w epoce J2000.0                  | $\theta_0 = 0.779\,057\,273\,264\,0 \times 2\pi\,rad$                               |
| Tempo zmian Kąta Obrotu Ziemi                     | $d\theta/dt = 1.002\,737\,811\,911\,354\,48 \times 2\pi\,rad \cdot doba_{UT1}^{-1}$ |

### Stałe nominalne

|                                     |  |
|-------------------------------------|--|
| Nominalny promień Słońca            | $\mathcal{R}_{\odot}^N = 6.957 \times 10^8\,m$                       |
| Nominalny parametr masy Słońca      | $(\mathcal{GM})_{\odot}^N = 1.327\,124\,4 \times 10^{20}\,m^3s^{-2}$ |
| Nominalny promień równikowy Ziemi   | $\mathcal{R}_{eE}^N = 6.3781 \times 10^6\,m$                         |
| Nominalny promień biegunowy Ziemi   | $\mathcal{R}_{pE}^N = 6.3568 \times 10^6\,m$                         |
| Nominalny promień równikowy Jowisza | $\mathcal{R}_{eJ}^N = 7.1492 \times 10^7\,m$                         |
| Nominalny promień biegunowy Jowisza | $\mathcal{R}_{pJ}^N = 6.6854 \times 10^7\,m$                         |
| Nominalny parametr masy Ziemi       | $(\mathcal{GM})_E^N = 3.986\,004 \times 10^{14}\,m^3s^{-2}$          |
| Nominalny parametr masy Jowisza     | $(\mathcal{GM})_J^N = 1.266\,865\,3 \times 10^{17}\,m^3s^{-2}$       |

### Najlepsze współczesne oszacowania

#### Naturalne stałe mierzone

Stała grawitacyjna  $G = 6.674\,28 \times 10^{-11} \pm 6.7 \times 10^{-15}\,m^3kg^{-1}s^{-2}$

#### Inne stałe

Współczynnik zmiany skali czasu od  $TCG$  do  $TCB$   $L_C = 1.480\,826\,867\,41 \times 10^{-8} \pm 2 \times 10^{-17}$

#### Stale ciała Systemu Słonecznego

|  |   |
|--|---|
| Parametr masy Słońca                               |   |
| zgodny z $TCB$                                     | $GM_S = 1.327\,124\,420\,99 \times 10^{20} \pm 1 \times 10^{10}\,m^3s^{-2}$ |
| zgodny z $TDB$                                     | $GM_S = 1.327\,124\,400\,41 \times 10^{20} \pm 1 \times 10^{10}\,m^3s^{-2}$ |
| Równikowy promień Ziemi <sup>4)</sup>              | $a_E = 6.378\,136\,6 \times 10^6 \pm 1 \times 10^{-1}\,m$                   |
| Współczynnik dynamiczny figury Ziemi <sup>4)</sup> | $J_2 = 1.082\,635\,9 \times 10^{-3} \pm 1 \times 10^{-10}$                  |
| Zmiana wiekowa współczynnika $J_2$                 | $dJ_2/dt = -3.0 \times 10^{-9} \pm 6 \times 10^{-10}\,stulecie^{-1}$        |
| Geocentryczna stała grawitacyjna <sup>4)</sup>     |   |
| zgodna z $TCB$                                     | $GM_E = 3.986\,004\,418 \times 10^{14} \pm 8 \times 10^5\,m^3s^{-2}$        |
| zgodna z $TT$                                      | $GM_E = 3.986\,004\,415 \times 10^{14} \pm 8 \times 10^5\,m^3s^{-2}$        |
| zgodna z $TDB$                                     | $GM_E = 3.986\,004\,356 \times 10^{14} \pm 8 \times 10^5\,m^3s^{-2}$        |
| Potencjał siły ciężkości na geoidzie <sup>4)</sup> | $W_0 = 6.263\,685\,60 \times 10^7 \pm 5 \times 10^{-1}\,m^2s^{-2}$          |
| Prędkość kątowna Ziemi <sup>4)</sup>               | $\omega = 7.292\,115 \times 10^{-5}\,rad\,s^{-1}$                           |

<sup>4)</sup> Por. z inną, przyjętą przez IUGG wartością wg GRS80.

|   |   |
|---|---|
| Stosunek masy Księżyca do masy Ziemi            | $M_M/M_E = 1.230\,003\,71 \times 10^{-2} \pm 4 \times 10^{-10}$ |
| Stosunek masy Słońca do masy Merkurego          | $M_S/M_{Me} = 6.023\,6 \times 10^6 \pm 3 \times 10^2$           |
| Stosunek masy Słońca do masy Wenus              | $M_S/M_V = 4.085\,237\,19 \times 10^5 \pm 8 \times 10^{-3}$     |
| Stosunek masy Słońca do masy Marsa              | $M_S/M_{Ma} = 3.098\,703\,59 \times 10^6 \pm 2 \times 10^{-2}$  |
| Stosunek masy Słońca do masy Jowisza            | $M_S/M_J = 1.047\,348\,644 \times 10^3 \pm 1.7 \times 10^{-5}$  |
| Stosunek masy Słońca do masy Saturna            | $M_S/M_{Sa} = 3.497\,901\,8 \times 10^3 \pm 1 \times 10^{-4}$   |
| Stosunek masy Słońca do masy Urana              | $M_S/M_U = 2.290\,298 \times 10^4 \pm 3 \times 10^{-2}$         |
| Stosunek masy Słońca do masy Neptuna            | $M_S/M_N = 1.941\,226 \times 10^4 \pm 3 \times 10^{-2}$         |
| Stosunek masy Słońca do masy Plutona            | $M_S/M_P = 1.365\,66 \times 10^8 \pm 2.8 \times 10^4$           |
| Stosunek masy Słońca do masy Eris               | $M_S/M_{Eris} = 1.191 \times 10^8 \pm 1.4 \times 10^6$          |
| Stosunek masy Ceres do masy Słońca              | $M_{Ceres}/M_S = 4.72 \times 10^{-10} \pm 3 \times 10^{-12}$    |
| Stosunek masy Pallas do masy Słońca             | $M_{Pallas}/M_S = 1.03 \times 10^{-10} \pm 3 \times 10^{-12}$   |
| Stosunek masy Vesta do masy Słońca              | $M_{Vesta}/M_S = 1.35 \times 10^{-10} \pm 3 \times 10^{-12}$    |
| Nachylenie ekliptyki do równika w epoce J2000.0 | $\varepsilon = 8.438\,140\,6 \times 10^4 \pm 1 \times 10^{-3}$  |

### Wielkości uzupełniające i dodatkowe

|  |                                       |
|--|---------------------------------------|
| Stała grawitacyjna Gaussa  | $k = 0.017\,202\,098\,95$             |
| Czas pokonywania przez światło astronomicznej jednostki długości   | $\tau_{au} = 499.004\,783\,806\,1\,s$ |
| Precesja ogólna w długości w epoce J2000.0 na stulecie juliańskie  | $p = 5028.796195$                     |
| Stała nutacji w epoce J2000.0                                      | $N = 9.2025$                          |
| Stała aberracji rocznej dla epoki J2000.0                          | $K = 20.49552$                        |
| Paralaksa Słońca ( $\pi_S = a_E/au$ )                              | $\pi_S = 8.794\,148$                  |
| Splaszczanie Ziemi <sup>4)</sup>                                   | $f = 1/298.256\,42$                   |
| Współczynnik dynamiczny Słońca                                     | $J_{2S} = 2 \times 10^{-7}$           |
| Masa Słońca ( $M_S = GM_S \cdot G^{-1}$ )                          | $M_S = 1.98842 \times 10^{30}\,kg$    |
| Stosunek masy Słońca do masy Ziemi ( $M_S/M_E = GM_S(GM_E)^{-1}$ ) | $M_S/M_E = 332\,946.04$               |
| Stosunek masy Słońca do masy układu Ziemia—Księżyc                 |                                       |
| $M_S/(M_E + M_M) = GM_S/(GM_E + M_M/M_E \cdot GM_E)$               | $M_S/(M_E + M_M) = 328\,901$          |

Stałe astronomiczne zamieszczone w niniejszym Roczniku zostały zaczerpnięte z uaktualnionej jesienią 2012 r. strony internetowej ([http://maia.usno.navy.mil/NSFA/NSFA\\_cbe.html](http://maia.usno.navy.mil/NSFA/NSFA_cbe.html)) Grupy Roboczej „Standardy Numeryczne Astronomii Fundamentalnej”. Są to wartości obowiązujące obecnie przy obliczeniach wymagających największej precyzji. Wartości stałych nominalnych zostały zaczerpnięte bezpośrednio z wprowadzającej je Rezolucji B3, ZG IAU, (Honolulu, 2015). Dodatkowo zamieszczono uzupełniającą listę stałych i wielkości pomocniczych — niektóre odniesione do poprzednio obowiązujących systemów. Mogą one być stosowane w obliczeniach nie wymagających najwyższych dokładności.

## Stałe Międzynarodowej Unii Geodezji i Geofizyki (IUGG) (dotyczące figury Ziemi GRS80)

### Stałe definiujące (dokładnie)

|                                      |  |
|--------------------------------------|--|
| Równikowy promień Ziemi              | $a_e = 6\,378\,137\text{ m}$                             |
| Geocentryczna stała grawitacyjna     | $GM = 3.986\,005 \times 10^{14}\text{ m}^3\text{s}^{-2}$ |
| Współczynnik dynamiczny figury Ziemi | $J_2 = 1.082\,63 \times 10^{-3}$                         |
| Prędkość kątowna obrotu Ziemi        | $\omega = 7.292\,115 \times 10^{-5}\text{ rad s}^{-1}$   |

### Stałe pochodne

|   |  |
|---|--|
| Splaszczanie Ziemi  | $f = 1/298.257\,222\,101$                                    |
| Przyspieszenie normalne siły ciężkości na równiku   | $\gamma_e = 9.780\,326\,771\,5\text{ ms}^{-2}$               |

Precesja w rektascensji na stulecie juliańskie ( $m = \dot{\zeta}_A + \dot{z}_A$ )

$$m = 4\,612''.160\,408 + 2''.783\,169\,4\,T + 0''.108\,859\,950\,T^2 - 0''.000\,138\,268\,T^3 - 0''.000\,003\,038\,5\,T^4 \quad (11)$$

Precesja w deklinacji na stulecie juliańskie ( $n = \dot{\theta}_A$ )

$$n = 2\,004''.191\,903 - 0''.858\,986\,8\,T - 0''.125\,467\,92\,T^2 - 0''.000\,028\,356\,T^3 - 0''.000\,000\,637\,T^4 \quad (12)$$

Średnie nachylenie Ekliptyki

$$\varepsilon_A = 84\,381''.406 - 46''.836\,769\,t - 0''.000\,183\,1\,T^2 + 0''.002\,003\,40\,T^3 - 0''.000\,000\,576\,T^4 - 0''.000\,000\,043\,4\,T^5 \quad (13)$$

**Wzory na zamianę jednostek czasu gwiazdowego średniego i średniego czasu słonecznego**

$$\frac{\text{interwał czasu gwiazdowego średniego}}{\text{interwał czasu słonecznego średniego}} = 1.002\,737\,909\,350\,795 + 5.9006 \times 10^{-11}\,T - 5.9 \times 10^{-15}\,T^2$$

$$\frac{\text{interwał czasu słonecznego średniego}}{\text{interwał czasu gwiazdowego średniego}} = 0.997\,269\,566\,329\,084 - 5.8684 \times 10^{-11}\,T + 5.9 \times 10^{-15}\,T^2 \quad (14)$$

Do przeliczenia interwałów czasu wyrażonego w jednostkach czasu średniego słonecznego na interwały czasu wyrażonego w jednostkach czasu średniego gwiazdowego oraz do zamiany w stronę przeciwną wykorzystuje się w praktyce zależność, że liczba dób gwiazdowych w roku zwrotnikowym jest dokładnie o jedność większa od liczby dób słonecznych

$$\begin{aligned} \text{rok zwrotnikowy} &= 366.242\,198\,797 \text{ średnich dób gwiazdowych} \\ &= 365.242\,198\,797 \text{ średnich dób słonecznych} \end{aligned}$$

Relację pomiędzy jednostką czasu słonecznego i jednostką czasu gwiazdowego wyraża współczynnik proporcjonalności

$$1 + \mu = \frac{366.242\,198\,797}{365.242\,198\,797} = 1.002\,737\,909\,3 \quad (15)$$

stąd

$$[\text{interwał czasu}]_{\text{śr. cz. gw.}} = (1 + \mu) \times [\text{interwał czasu}]_{\text{śr. cz. sł.}} \quad (16)$$

Podobnie dla przejścia od jednostek czasu gwiazdowego do jednostek czasu słonecznego

$$[\text{interwał czasu}]_{\text{śr. cz. sł.}} = 1/(1 + \mu) \times [\text{interwał czasu}]_{\text{śr. cz. gw.}}$$

lub

$$[\text{interwał czasu}]_{\text{śr. cz. sł.}} = (1 - \mu') \times [\text{interwał czasu}]_{\text{śr. cz. gw.}} \quad (17)$$

gdzie  $\mu' = 0.002\,730\,433\,6$

<sup>5)</sup> Aby otrzymać rektascensję w systemie FK5, poprawkę należy dodać do rektascensji wyrażonej w systemie FK4.

# OBJAŚNIENIA

## CZĘŚĆ OGÓLNA

W ostatnich kilku dziesięcioleciach zaszły ważne zmiany w poznaniu ruchu obrotowego Ziemi — nastąpił ogromny postęp w zakresie osiąganych precyzji i rozdzielczości czasowych obserwacji, jak również w strategiach i technologii ich opracowywania. Istotną zmianą jest także fakt, że począwszy od 1980 roku ruch bieguna jest monitorowany w sposób ciągły przy użyciu VLBI i dostarczane są aktualne pozycje bieguna w odniesieniu do układu niebieskiego. Używanie układu odniesienia opartego na równiku niebieskim (określonym przez średnią w sensie ruchów bieguna oś obrotu Ziemi) oraz punkcie początkowym zdefiniowanym położeniem ekliptyki (punkt średniej równonocy wiosennej) stawało się coraz trudniejsze, a nawet prowadziło do degradacji precyzji osiąganey w obserwacjach astronomicznych, szczególnie, że istniało kilka realizacji punktu równonocy: dynamiczne i katalogowe. Dodatkowo konstrukcja katalogów nie zapewniała całkowitej eliminacji obrotu definiowanych przez nie układów odniesienia. W ślad za postępem w dziedzinie obserwacji, w latach 1990–1999 nastąpiła również ogromna poprawa w modelowaniu teoretycznym, osiągającym dokładności na poziomie  $\mu s$ .

### 1. SYSTEMY ODNIESIENIA

XXI Zgromadzenie Generalne IAU (Buenos Aires, 1991) przyjęło w Rezolucji A4 pakiet 9 spójnych Rekomendacji specyfikujących nowe niebieskie systemy odniesienia w czterowymiarowej czasoprzestrzeni i związane z nimi skale czasu z uwzględnieniem ogólnej teorii względności. W Rekomendacji 1 zaleciło ono zdefiniowanie w ramach ogólnej teorii względności kilku układów współrzędnych  $(x^0 = ct, x^1, x^2, x^3)$  w czasoprzestrzeni w taki sposób, aby w każdym układzie współrzędnych o początku w barycentrum dowolnego zbioru mas, kwadrat interwału  $ds$  między zdarzeniami, był wyrażony co najmniej ze stopniem przybliżenia podanym według wzoru:

$$ds^2 = -c^2 d\tau^2 = -(1 - 2U/c^2)(dx^0)^2 + (1 + 2U/c^2)[(dx^1)^2 + (dx^2)^2 + (dx^3)^2] \quad (18)$$

gdzie  $t$  jest współrzędną czasową (czasem współrzędnych<sup>6)</sup>),  $\tau$  jest czasem własnym (nazywanym również czasem prawdziwym) danego punktu w przestrzeni (czas pomiędzy dwoma zdarzeniami występującymi w tym samym punkcie przestrzeni), a  $U$  jest sumą potencjału grawitacyjnego tego układu mas oraz, generowanego przez ciała zewnętrzne względem układu, potencjału pływowego zanikającego w barycentrum. Interwał  $ds$  z formalnego punktu widzenia może być traktowany jako odległość dwóch punktów w abstrakcyjnej czterowymiarowej przestrzeni z wprowadzoną przez Minkowskiego geometrią pseudo-euklidesową. W Rekomendacji 2 zasygnalizowana została potrzeba zdefiniowania barycentrycznego systemu współrzędnych o początku w środku mas Układu Słonecznego z czasem współrzędnych barycentrycznych  $TCB$  (Rekom. 3) oraz geocentrycznego systemu odniesienia o początku w środku mas Ziemi z czasem współrzędnych geocentrycznych  $TCG$  (Rekom. 3). Jednocześnie zalecono aby te systemy nie podlegały obrotom względem zbioru odległych obiektów pozagalaktycznych, aby współrzędne czasowe tych systemów były wyprowadzone ze skali czasu realizowanej przez działające na Ziemi zegary atomowe oraz aby jednostkami fizycznymi w tych systemach były jednostki SI. Sformułowano również czterowymiarową transformację pomiędzy  $TCB$  i  $TCG$ . Za czas odniesienia dla pozornych, geocentrycznych efemeryd przyjęto czas ziemski  $TT$  oraz określono relację między  $TCG$  i  $TT$  (Rekom. 4). Dodatkowo w Rekomendacji 7 zalecono aby nowy, barycentryczny system odniesienia był możliwie bliski równikowi i punktowi równonocy wiosennej systemu FK5 odniesionym do epoki J2000.0, tj. aby podstawowa płaszczyzna tego systemu (płaszczyzna  $xy$  odpowiadająca płaszczyźnie równika niebieskiego w katalogowych systemach odniesienia) znalazła się możliwie blisko płaszczyzny średniego równika na epokę J2000.0, zaś punkt początkowy liczenia rektascensji  $CEO$  (odpowiednik punktu równonocy wiosennej w katalogowych układach odniesienia, czyli kierunek osi  $x$ ) znalazł się możliwie blisko dynamicznej równonocy wiosennej na epokę J2000.0. W tej samej rezolucji podkreślono, że utworzony system ma być dostępny dla astrometrii w zakresie fal radiowych i widma widzialnego.

---

<sup>6)</sup> Czas współrzędnych nie jest mierzalnym.

**Międzynarodowy Niebieski System Odniesienia (ICRS)** zdefiniowany oraz przyjęty w Rezolucji B2 XXIII Zgromadzenia Generalnego IAU (Kyoto, 1997) („The extragalactic reference system of the International Earth Rotation Service (ICRS)”, Arias E.F. et al., A&A 303, 604 (1995)) jest od 1 stycznia 1998 roku obowiązującym niebieskim systemem odniesienia. Kinematyczną realizacją *ICRS* przeznaczoną do zastosowań praktycznych jest **Międzynarodowy Niebieski Układ Odniesienia (ICRF)**. Ta sama rezolucja zatwierdziła **katalog Hipparcos** jako podstawową realizację *ICRS* w zakresie widma optycznego. Uchwalona trzy lata później przez XXIV Zgromadzenie Generalne IAU Rezolucja B1.3 (Manchester, 2000) określa ponadto definicję *ICRS* dopasowaną do wyższych wymagań dokładnościowych oraz do współczesnego formalizmu ogólnej teorii względności, wprowadzając **Barycentryczny Niebieski System Odniesienia (BCRS)** oraz **Geocentryczny Niebieski System Odniesienia (GCRS)**, a także transformację między tymi systemami.

*ICRS* jest systemem kinematycznym, ponieważ jest zdefiniowany poprzez pozycje odległych obiektów pozagalaktycznych; dodatkowo ruchy własne tych obiektów są znacznie mniejsze aniżeli dokładność obserwacji tych obiektów. W systemie *ICRS*, kierunki do obiektów w odległych galaktykach nie podlegają globalnemu obrotowi względem tych obiektów. Zgodnie z definicją jest on czasoprzestrzennym systemem niezależnym od położenia osi obrotu Ziemi, a także od położenia osi ekliptyki. Czasoprzestrzeń w *ICRS* jest określona geometrycznie za pomocą tensora metrycznego (oddzielnie dla *BCRS* i dla *GCRS*) w ujęciu ogólnej teorii względności. Zgodnie z Rezolucją 2 XXVI Zgromadzenia Generalnego IAU (Praga, 2006) dla wszystkich praktycznych zastosowań przyjmuje się orientację *BCRS* zgodnie z orientacją osi *ICRS*. Orientacja *GCRS* jest wyznaczana z orientacji *BCRS* zorientowanej względem *ICRS*. Osie tych systemów spełniają kinematyczny warunek zerowego wzajemnego obrotu. Oba systemy mają też różne czasy współrzędnych: *TCB* i *TCG*. Odpowiadające sobie osie systemów *BCRS* i *GCRS* są wzajemnie powiązane współczynnikiem skali. Ponadto *BCRS* jest z założenia systemem kinematycznie ustalonym. Nie jest on odniesiony do epoki, która byłaby związana z pozycją osi systemu jak to ma miejsce w przypadku systemu katalogowego, np. FK5. Pozycje w systemie *ICRS* odgrywają rolę stosowanych dotychczas średnich pozycji katalogowych odniesionych do średniego równika i średniej równonocy wiosennej na standardową epokę, lecz w ich wypadku epoka we wspomnianym sensie nie ma zastosowania. Zmienność pozycji w systemie *ICRS* spowodowana jest wyłącznie ruchem własnym gwiazd z uwzględnieniem prędkości radialnej. Orientacja geocentrycznego systemu niebieskiego *GCRS* używanego do transformacji między systemami niebieskim i ziemskim, w stosunku do *BCRS* spełnia kinematyczny warunek braku globalnego obrotu geocentrycznych kierunków do obiektów realizujących *ICRS*. *GCRS* jest zatem nieobracającym się systemem geocentrycznym przeznaczonym do monitorowania parametrów ruchu obrotowego Ziemi EOP. System ten nie podlega globalnej rotacji i nie zależy już od ruchu Ziemi, jak to miało miejsce w przypadku FK5.

*ICRF* został zdefiniowany z dokładnością około  $30 \mu\text{as}$  poprzez pozycje 212 definiujących radioźródeł, określone w oparciu o obserwacje VLBI. Umowny biegun *ICRS*, nazwany Konwencjonalnym Biegunem Odniesienia *CRP* (kierunek prostopadły do podstawowej płaszczyzny układu — płaszczyzny *xy*) choć jest bardzo zbliżony do średniego bieguna na epokę J2000.0 to jednak dokładnie się z nim nie pokrywa. Bieguny te są wzajemnie przesunięte o  $17.1 \text{ mas}$  w kierunku  $0^\circ$  i  $5.1 \text{ mas}$  w kierunku  $90^\circ$ . Podobna zgodność zachodzi pomiędzy umownym biegunem *ICRS* i biegunem katalogu FK5. Ocenia się ją na  $\pm 50 \text{ mas}$ . Punkt początkowy liczenia rektascensji w *ICRS*, który określa kierunek osi *x* tego systemu, jest przesunięty w stosunku do punktu równonocy katalogu FK5 o  $22.9 \pm 2.3 \text{ mas}$ .

Na mocy Rezolucji B3 XXVII Zgromadzenia Generalnego IAU w Rio de Janeiro w 2009 r. druga realizacja Międzynarodowego Niebieskiego Układu Odniesienia *ICRF2* zastąpiła od 1 stycznia 2010 r. *ICRF* jako fundamentalna astrometryczna realizacja *ICRS*. *ICRF2* zdefiniowano poprzez precyzyjnie wyznaczone pozycje 3414 zwartych astronomicznych radioźródeł, których poziom szumów nie przekraczał  $40 \mu\text{as}$ , zaś stabilność jego osi kształtowała się na poziomie  $10 \mu\text{as}$ . Dopasowania *ICRF2* do *ICRS* dokonano przy użyciu 138 stabilnych radioźródeł, wspólnych dla *ICRF2* i *ICRF-Ext2*. *ICRF2* był utrzymywany przy wykorzystaniu 295 definiujących radioźródeł wybranych w oparciu o kryterium stabilności oraz braku rozwiniętej wewnętrznej struktury radioźródła. Stabilność wspomnianych radioźródeł oraz ich bardziej równomierny rozkład na sferze niebieskiej eliminowały dwie najpoważniejsze słabości *ICRF*.

Od 1 stycznia 2019 r. fundamentalną realizacją Międzynarodowego Niebieskiego Systemu Odniesienia (*ICRS*) jest *ICRF3* — trzecia realizacja Międzynarodowego Niebieskiego Układu Odniesienia (Rezolucja B2 XXX Zgromadzenia Generalnego IAU, Wiedeń, 2018). Przy opracowaniu *ICRF3* po raz pierwszy uwzględniono efekt galaktocentrycznego przyspieszenia Układu Słonecznego. Rozszerzono również zakres częstotliwości obserwowanych radioźródeł. *ICRF3* składa się z katalogów dokładnych pozycji radioźródeł obserwowanych w trzech pasmach częstotliwości. Oprócz katalogu głównego w paśmie X/S (8.4/2.3 GHz) zawierającego pozycje 4536 radioźródeł (wzrost o 33% w stosunku do *ICRF2*) z poziomem szumu wynoszącym  $30 \mu\text{as}$  (poprawa o 25% w stosunku do *ICRF2*), z których 303 zidentyfikowano jako radioźródła definiujące, w skład *ICRF3* wchodzi dodatkowo dwa katalogi: jeden w paśmie K (24 GHz) zawierający pozycje 824 radioźródeł

rozproszonych po całym niebie z poziomem szumu wynoszącym  $30\mu\text{s}$  i  $50\mu\text{s}$  odpowiednio w rektascensji i deklinacji oraz drugi w paśmie Ka/X (32/8.4 GHz) zawierający pozycje 678 radioźródeł.

Ziemi system odniesienia jest systemem przestrzennym obracającym się wraz z Ziemią. W systemie tym pozycje punktów związanych z powierzchnią Ziemi są określone przez współrzędne, które podlegają jedynie małym zmianom w czasie spowodowanym przez efekty geofizyczne (ruchy tektoniczne, deformacje pływowe). Realizacją ziemskiego systemu odniesienia jest ziemski układ odniesienia określony przez zbiór punktów o precyzyjnie wyznaczonych współrzędnych oraz ich zmianach w czasie, w ziemskim systemie odniesienia.

**Konwencjonalny Ziemski System Odniesienia** (*CTRS*) został zdefiniowany w Rezolucji 2 XX Zgromadzenia Generalnego IUGG (Wiedeń, 1991). Zgodnie z przyjętą rezolucją *CTRS* jest quasi-kartezjańskim systemem zdefiniowanym przez przestrzenny obrót względem nieobrcającego się systemu geocentrycznego (*GCRS* — zdefiniowany przez IAU). Czasem współrzędnych *CTRS* jest *TCG* — czas współrzędnych *GCRS*. Początkiem *CTRS* jest środek mas Ziemi określony z uwzględnieniem oceanów i atmosfery. *CTRS* jest systemem kinematycznym nie podlegającym globalnemu, residualnemu obrotowi względem ruchów poziomych na powierzchni Ziemi.

**Geocentryczny Ziemski System Odniesienia** (*GTRS*) stanowi uściślenie *CTRS*, a jednocześnie dopasowanie ziemskiego systemu odniesienia do jednolitego formalizmu użytego do zdefiniowania niebieskich systemów odniesienia. *GTRS* został zatwierdzony w Rezolucji 2 XXIV Zgromadzenia Generalnego IUGG (Perugia, 2007) jako system czasoprzestrzenny zdefiniowany w zgodności z Rezolucją B1.3 Zgromadzenia Generalnego IAU w 2000 r.

**Międzynarodowy Ziemski System Odniesienia** (*ITRS*) jest określony przez zbiór zaleceń i ustaleń wraz z opisem modeli niezbędnych do zdefiniowania początku, skali, orientacji i zmienności w czasie *CTRS* monitorowanego przez IERS. Jest to system geocentryczny, którego jednostką długości jest metr (SI). W myśl postanowień IUGG i IAU (1991) skala *ITRS* jest spójna z czasem współrzędnych geocentrycznych *TCG*. Orientacja *ITRS* została początkowo zdefiniowana przez orientację BIH 1984.0, zaś jej zmienność w czasie jest określona poprzez zastosowanie warunku, iż globalna suma poziomych ruchów tektonicznych nie zawiera składowych obrotu. Zgodnie z Rezolucją 2 Zgromadzenia Generalnego IUGG (Perugia, 2007) *ITRS* jest zdefiniowany jako szczególnie Geocentryczny Ziemski System Odniesienia (*GTRS*), którego orientacja jest operacyjnie utrzymywana w ciągłości z poprzednimi uzgodnieniami międzynarodowymi (orientacja BIH) oraz przyjęty jako preferowany *GTRS* do zastosowań naukowych i praktycznych. Praktycznymi realizacjami *ITRS* są międzynarodowe ziemskie układy odniesienia *ITRF*. Poszczególne rozwiązania *ITRF* (*ITRF88*, *ITRF89*, ... *ITRF96*, *ITRF97*, *ITRF2000*, *ITRF2005*, *ITRF2008* i *ITRF2014*) są opracowywane przez ośrodki obliczeniowe IERS w oparciu o obserwacje VLBI, LLR, SLR, GPS i DORIS. Każde kolejne rozwiązanie *ITRF* zawiera pozycje i prędkości stacji obserwacyjnych oraz pełną macierz kowariancji. Rozwój sieci *ITRF* w okresie ostatnich kilkunastu lat (5-krotny wzrost liczby stacji obserwacyjnych i poprawa ich przestrzennego rozkładu) oraz poprawa precyzji wyznaczenia pozycji i prędkości stacji dzięki zwiększaniu materiału obserwacyjnego i ulepszaniu strategii i metod opracowania obserwacji powodują znaczącą poprawę w kolejnych rozwiązaniach *ITRF*. Parametry transformacji pomiędzy układami *ITRF* są wyznaczane przez IERS i publikowane w IERS Conventions.

Transformacja pomiędzy ziemskim systemem odniesienia (do niego odnoszą się obserwacje) a niebieskim systemem odniesienia (system quasi-inercjalny, w którym podawane są pozycje gwiazd) tradycyjnie jest wykonywana w trzech zasadniczych etapach. W pierwszym etapie **system obserwacyjny** zdefiniowany przez „równik obserwacyjny” i „zerowy południk obserwacyjny” jest przeprowadzany przy pomocy parametrów opisujących ruch bieguna ziemskiego w **system pośredni** zdefiniowany przez „równik pośredni” i „zerowy południk pośredni”. Następnym krokiem jest **obrót** systemu pośredniego wokół osi „równika pośredniego” o kąt reprezentujący obrót Ziemi wokół własnej osi. Obrócony w ten sposób system pośredni staje się geocentrycznym systemem niebieskim, do którego odnoszą się tzw. miejsca pozorne. W ostatnim kroku system pośredni (a dokładnie utworzony w poprzednim kroku geocentryczny system niebieski) jest przeprowadzany w **system quasi-inercjalny** przy pomocy parametrów opisujących precesję i nutację. W transformacji są uwzględniane dodatkowo efekty aberracji i paralaksy, ruch własny gwiazd i efekty relatywistyczne.

Do 1980 roku rolę „równika obserwacyjnego” odgrywał równik tzw. międzynarodowego umownego średniego bieguna północnego Ziemi *CIO\** zdefiniowanego przez szerokości astronomiczne 5 obserwatoriów uczestniczących w Międzynarodowej Służbie Szerokości ILS, umieszczonych na równoleżniku  $39^{\circ}09'$ , zaś „zerowemu południkowi obserwacyjnemu” odpowiadał średni południk Greenwich zdefiniowany przez długości astronomiczne około 50 obserwatoriów uczestniczących w programie BIH. Tak zdefiniowany równik *CIO\** i „zerowy południk obserwacyjny” określały kierunki osi konwencjonalnego systemu ziemskiego *CTS* (od 1967 roku — *GRS67*). „Równikowi pośredniemu” odpowiadał równik chwilowy, którego oś

stanowiła chwilowa oś obrotu Ziemi, zaś chwilowy południk Greenwich służył jako „zerowy południk pośredni”. Parametry ruchu bieguna wykorzystywane do przeprowadzenia bieguna *CIO\** w biegun chwilowy były dostarczane przez Międzynarodową Służbę Ruchu Bieguna IPMS (poprzedniczkę IERS). Obrót systemu pośredniego odbywał się wokół chwilowej osi obrotu Ziemi o kąt równy prawdziwemu czasowi gwiazdowemu Greenwich *GST* (lub *GAST*) będącemu nieliniową funkcją *UT1*. Przeprowadzał on system ziemski w system niebieski, w którym była wyrażona pozycja pozorna i, po usunięciu wpływu aberracji rocznej i paralaksy rocznej, tzw. pozycja prawdziwa (barycentryczna). Uwzględnienie następnie nutacji prowadziło do transformacji do systemu niebieskiego, w którym była wyrażona tzw. pozycja średnia na epokę obserwacji, zaś uwzględnienie precesji wiązało się z kolejną transformacją systemu niebieskiego z epoki obserwacji do epoki katalogu fundamentalnego (FK4, a od 1984 r. FK5).

Opisana powyżej procedura transformacji systemu ziemskiego do niebieskiego uległa zasadniczym zmianom na skutek postępu w monitorowaniu ruchu obrotowego Ziemi oraz rozwoju teorii opisujących zjawiska precesji (model IAU1976) i nutacji (teoria nutacji IAU1980), odnoszących się do Niebieskiego Bieguna Efemerydalnego *CEP*. *CEP* został zdefiniowany jako biegun pośredniego systemu odniesienia (pomiędzy systemem ziemskim i niebieskim), który rozdziela ruch bieguna ziemskiego systemu odniesienia na dwie części. Część niebieska dotyczyła ruchu *CEP* względem niebieskiego systemu odniesienia z uwzględnieniem wszystkich wyrazów długookresowych (precesja/nutacja wymuszona) i zawierała wyrazy o okresach dłuższych od 2 dób (tj. o częstotliwościach pomiędzy  $-0.5$  i  $+0.5$  cykli na dobę gwiazdową). Część ziemską dotyczyła ruchu *CEP* względem ziemskiego systemu odniesienia z uwzględnieniem wszystkich wyrazów długookresowych (ruch bieguna) i zawierała wyrazy o okresach dłuższych od 2 dób (tj. o częstotliwościach pomiędzy  $-0.5$  i  $+0.5$  cykli na dobę gwiazdową). Podobnie jak poprzednio rolę „równika obserwacyjnego” oraz „zerowego południka obserwacyjnego” odgrywały odpowiednio równik *CIO\** i średni południk Greenwich BIH konwencjonalnego systemu ziemskiego. Miejsce chwilowego równika jako „równika pośredniego” zajął odpowiednio równik określony przez bliski chwilowemu biegunowi Ziemi *IRP* Niebieski Biegun Efemerydalny *CEP*, którego parametry położenia względem bieguna konwencjonalnego systemu ziemskiego początkowo były dostarczane przez IPMS, a następnie od 1988 roku przez IERS. Miejsce chwilowego południka Greenwich jako „zerowego południka pośredniego” zajął chwilowy południk określony poprzez uwzględnienie poprawki z tytułu ruchu bieguna do południka Greenwich BIH konwencjonalnego systemu ziemskiego GRS80. Obrót systemu pośredniego odbywał się wokół osi *CEP* albo o kąt równy *GST* w odniesieniu do punktu równonocy wiosennej, albo o kąt równy tzw. Kątowi Obrotu Ziemi *ERA* występującemu również pod nazwą kąta gwiazdowego (w odniesieniu do Niebieskiego Efemerydalnego Punktu Początkowego *CEO* — nieobracającego się punktu początkowego na równiku *CEP* — odpowiednika punktu równonocy wiosennej jako punktu początkowego, od którego liczona jest rektascensja). Obrót ten przeprowadzał pośredni system ziemski w system niebieski. Podobnie jak w procedurze sprzed 1980 roku, po usunięciu wpływu aberracji rocznej i paralaksy rocznej, uwzględnienie nutacji i precesji, według jednak nowych bardziej dokładnych teorii dopasowanych do definicji *CEP*, a także ruchu własnego i efektów relatywistycznych przeprowadzało kolejno system pośredni w system niebieski na epokę obserwacji, a następnie na epokę katalogu.

Kolejne zmiany w procedurze transformacji systemu ziemskiego do niebieskiego zaszły w wyniku dalszego wzrostu dokładności teorii do poziomu  $\mu\text{as}$ , jaki nastąpił w latach 1990–1999 oraz rosnących wymagań dokładnościowych. Definicja *CEP* przestała być spójna z precyzją i rozdzielczością przestrzenną współczesnych technik obserwacyjnych, a także z dokładnością teorii i częstotliwością włączonych w nie wyrazów. Pełniejsze wykorzystanie opracowanej przez Guinot koncepcji kinematycznie zdefiniowanego punktu nazwanego Nieobracającym się Punktem Początkowym *NRO* posłużyło do sformułowania bardziej rozwiniętej definicji *CEP* — Pośredniego Bieguna Niebieskiego *CIP* oraz *CEO*, a także zdefiniowania punktu początkowego dla długości w systemie ziemskim, któremu nadano nazwę Ziemskiego Efemerydalnego Punktu Początkowego *TEO*. Opracowano również spójną z tymi definicjami nową łączną teorię precesyjno-nutacyjną IAU2000, definicję *CIP* oraz definicję parametrów opisujących ruch bieguna. Parametry ruchu bieguna dają się obecnie wyznaczać z dokładnością lepszą od milisekundy łuku na podstawie kilkugodzinnych obserwacji GPS i VLBI. Jednocześnie wyrazy o okresach dobowych i sub-dobowych występujące zarówno w opisie nutacji jak i ruchu bieguna dają się wyznaczyć z dokładnością mikrosekund łuku. Aby sprostać wysokim wymaganiom dokładnościowym dotychczas stosowany w modelowaniu matematycznym rozdział zjawiskowy pomiędzy nutacją swobodną i wymuszoną został zastąpiony rozdziałem uwzględniającym charakterystykę częstotliwościową oddzielnych składowych tych efektów. Zgodnie z Rezolucją B1.7 IAU (Manchester, 2000) Pośredni Biegun Niebieski *CIP* rozdziela ruch bieguna ziemskiego systemu odniesienia w niebieskim systemie odniesienia na dwie części, z których jedna w postaci modelu matematycznego zawiera wyrazy precesyjne oraz część wyrazów nutacji wymuszonej, druga zaś wyrazy nutacji swobodnej, wyznaczone przez IERS jako parametry ruchu bieguna, efekty pływów oceanicznych oraz pozostałe wyrazy nutacji wymuszonej. Część zawierająca wszystkie wyrazy o okresach dłuższych od 2 dób (tj. o częstotliwościach pomiędzy  $-0.5$  i  $+0.5$  cykli na dobę gwiazdową) została określona

jako precesja/nutacja, czyli ruch *CIP* względem systemu niebieskiego *GCRS*. Część zaś zawierająca wszystkie wyrazy ruchu wstecznego spoza pasma dobowego (tj. o częstotliwościach mniejszych od  $-1.5$  i większych od  $-0.5$  cykli na dobę gwiazdową) została określona jako ruch bieguna, czyli ruch *CIP* względem systemu ziemskiego *ITRS*.

Od 1 stycznia 2003 roku, na mocy Rezolucji B1.7 IAU (Manchester, 2000), obowiązuje nowa procedura transformacji systemu ziemskiego w system niebieski. Jako „równik obserwacyjny” przyjmuje się równik *ITRS*, zaś południk zerowy *ITRS* odgrywa rolę „zerowego południka obserwacyjnego”. Biegunem systemu pośredniego *IRS* jest Pośredni Biegun Niebieski *CIP*, którego parametry położenia względem bieguna *ITRS* są obliczane w oparciu o dane dostarczane przez IERS. Transformacja *ITRS* do *IRS<sub>ZIEMSKI</sub>* określa położenie *TEO* (dokładna realizacja chwilowego zerowego południka pośredniego) na równiku *CIP* zgodnie z kinematyczną definicją *NRO* w *ITRS* gdy *CIP* porusza się względem *ITRS* pod wpływem ruchu bieguna. Obrót systemu pośredniego *IRS* odbywa się wokół osi *CIP* o kąt równy **Kątowi Obrotu Ziemi** (*ERA*) będącemu liniową funkcją *UT1* i przeprowadza system *IRS<sub>ZIEMSKI</sub>* w system *IRS<sub>NIEBIESKI</sub>*, w którym jest określane miejsce pozorne. Uwzględnienie precesji/nutacji według teorii IAU2000 przeprowadza ten system do Geocentrycznego Niebieskiego Systemu Odniesienia *GCRS*. Dodatkowo z *GCRS* do Barycentrycznego Niebieskiego Systemu Odniesienia *BCRS* przechodzi się przez zastosowanie post-newtonowskiej transformacji współrzędnych narzuconej przez formę odpowiednich tensorów metrycznych obu systemów (Rezolucja B1.3 IAU, 2000).

Na mocy Rezolucji 1 Zgromadzenia Generalnego IAU (Praga, 2006) dokonano kolejnej modyfikacji procedury transformacji systemu ziemskiego w system niebieski. Polega ona na zastąpieniu części precesyjnej modelu precesyjno-nutacyjnego IAU2000 teorią precesyjną P03. Zmodyfikowana procedura transformacji obowiązuje od 1 stycznia 2009 r. Z kolei, na mocy Rezolucji 2 IAU (Praga, 2006) terminy *CEO* i *TEO* zostały zastąpione odpowiednio przez *CIO* — Niebieski Pośredni Punkt Początkowy i *TIO* — Ziemski Pośredni Punkt Początkowy.

Zależność pomiędzy wektorem jednostkowym  $\mathbf{e}_{ITRS}$  w *ITRS* i jego obrazem  $\mathbf{e}_{GCRS}$  w *GCRS* wyraża się przez transformację

$$\mathbf{e}_{GCRS} = Q(t) R(t) W(t) \mathbf{e}_{ITRS} \quad (19)$$

gdzie  $W(t)$ ,  $R(t)$  i  $Q(t)$  są macierzami transformacji wyrażającymi odpowiednio ruch *CIP* względem systemu ziemskiego *ITRS*, obrót systemu pośredniego *IRS* wokół osi *CIP* oraz ruch *CIP* względem systemu niebieskiego *GCRS*. Parametr czasowy  $t$  jest zdefiniowany następująco:

$$t = (JD(TT) - 2000 \text{ styczeń } 1^d 12^h TT) \text{ dób } / 36\,525 \quad (20)$$

zgodnie z Rezolucją C7 IAU (Haga, 1994), która zaleciła aby epoka J2000.0 była zdefiniowana w środku mas Ziemi i aby 2000 styczeń  $1.5 TT = JD\,2\,451\,545.0 TT$ .

Macierze transformacji pomiędzy systemami ziemskim i niebieskim dają się wyrazić w funkcji macierzy obrotowych  $R_1(\xi_1)$ ,  $R_2(\xi_2)$  i  $R_3(\xi_3)$  reprezentujących obroty odpowiednio wokół osi  $x$ ,  $y$  i  $z$  układu o kąty  $\xi_1$ ,  $\xi_2$ ,  $\xi_3$  dodatnie w kierunku przeciwnym do ruchu wskazówek zegara w przypadku stosowania układów prawoskrętnych. I tak

$$R_1(\xi_1) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \xi_1 & \sin \xi_1 \\ 0 & -\sin \xi_1 & \cos \xi_1 \end{pmatrix} \quad R_2(\xi_2) = \begin{pmatrix} \cos \xi_2 & 0 & -\sin \xi_2 \\ 0 & 1 & 0 \\ \sin \xi_2 & 0 & \cos \xi_2 \end{pmatrix} \quad R_3(\xi_3) = \begin{pmatrix} \cos \xi_3 & \sin \xi_3 & 0 \\ -\sin \xi_3 & \cos \xi_3 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad (21)$$

Macierz  $W(t)$  ma postać

$$W(t) = R_3(-s') R_2(x_p) R_1(y_p) \quad (22)$$

gdzie  $x_p$  i  $y_p$  są współrzędnymi *CIP* w *ITRS* na epokę  $t$  i są zdefiniowane jako

$$(x_p, y_p) = (x_{IERS}, y_{IERS}) + (\Delta x, \Delta y)_{\text{tidal}} + (\Delta x, \Delta y)_{\text{nutation}} \quad (23)$$

przy czym  $(x_{IERS}, y_{IERS})$  są współrzędnymi bieguna dostarczanych przez IERS (dostępne w biuletynach IERS),  $(\Delta x, \Delta y)_{\text{tidal}}$  są składowymi pływowymi wynikającymi z pływów oceanicznych, zaś  $(\Delta x, \Delta y)_{\text{nutation}}$  są wyłączonymi z modelu precesyjno-nutacyjnego IAU2006 składowymi nutacji wymuszonej. Poprawki  $(\Delta x, \Delta y)_{\text{tidal}}$  z tytułu dobowych i sub-dobowych efektów ruchu bieguna wywołanych pływami oceanicznymi można obliczyć korzystając z procedury dostępnej na stronach

Rys. 1 Schemat procesu transformacji od systemów niebieskich do ziemskich

internetowych IERS (<http://www.iers.org>). Wielkości  $(\Delta x, \Delta y)_{\text{nutatation}}$  reprezentujące dobowe i sub-dobowe wyrazy nutacyjne w ruchu bieguna można obliczyć korzystając z parametrów podanych w tablicy 5.1 IERS Conventions 2003. Wielkość  $s'$  określa spowodowaną przez ruch *CIP* względem *ITRS* zmianę pozycji *TIO* na równiku *CIP* zgodnie z wyrażeniem

$$s'(t) = \frac{1}{2} \int_{t_0}^t (x_p \dot{y}_p - \dot{x}_p y_p) dt \quad (24)$$

Ponieważ wielkość  $s'$  jest bardzo mała (rzędu  $0.1 \text{ mas/stulecie}$ ) można ją wyznaczyć z przybliżonego wzoru

$$s'(t) = -0.0015 (a_c^2/1.2 + a_a^2) t \quad (25)$$

gdzie  $a_c$  i  $a_a$  są średnimi amplitudami (w sekundach łuku) odpowiednio ruchu Chandlera i rocznego w badanym okresie od  $t_0$  do  $t$ , przy czym  $t$  jest wyrażone w stuleciach juliańskich. Korzystając z aktualnych, średnich amplitud ruchów Chandlera i rocznego  $s' = -47 \mu\text{as} \times t$ .

Macierz  $R(t)$  ma postać

$$R(t) = R_3(-\theta) \quad (26)$$

gdzie  $\theta$  jest Kątem Obrotu Ziemi *ERA*, który oblicza się w oparciu o *UTC* (wyznaczone z *TT*) oraz dostarczanych przez IERS poprawek  $[UT1 - UTC]_{\text{IERS}}$  jako liniowa funkcja *UT1*

$$\theta(T_u) = 2\pi (0.779\,057\,273\,264\,0 + 1.002\,737\,811\,911\,354\,48\,T_u) \quad (27)$$

gdzie

$$T_u = JD(UT1) - 2\,451\,545.0 \quad (28)$$

oraz

$$UT1 = UTC + [UT1 - UTC]_{\text{IERS}} \quad (29)$$

Macierz  $Q(t)$  ma postać

$$Q(t) = R_3(-E)R_2(-d)R_3(E)R_3(s) \quad (30)$$

gdzie  $E$  i  $d$  są współrzędnymi sferycznymi *CIP* w *GCRS*. Składowe wektora jednostkowego *CIP* w *GCRS*, w układzie kartezjańskim mają postać

$$\begin{aligned} X &= \sin d \cos E \\ Y &= \sin d \sin E \\ Z &= \cos d \end{aligned} \quad (31)$$

Parametr  $s$  jest wielkością określającą zmianę w czasie położenia *CIO* na równiku *CIP* spowodowaną przez ruch *CIP* względem *GCRS*. Z zachowaniem dokładności na poziomie  $1 \mu\text{as}$  parametr ten wyraża się wzorem

$$s(t) = -\frac{1}{2} [X(t)Y(t) - X(t_0)Y(t_0)] + \int_{t_0}^t \dot{X}(t)Y(t)dt - ([\sigma_0 N_0] - [\Sigma_0 N_0]) \quad (32)$$

gdzie  $t_0 = \text{J2000.0}$

W celu zapewnienia ciągłości 1 stycznia 2003 roku z obliczeniami wykonywanymi w oparciu o poprzednie procedury precesyjno-nutacyjne, dla stałej  $s_0 = [\sigma_0 N_0] - [\Sigma_0 N_0]$  przyjmuje się wartość  $+94 \mu\text{as}$  ( $[\sigma_0 N_0]$  odpowiada kątowi pomiędzy  $\sigma_0$  — pozycją *CIO* na równiku *CIP* na epokę J2000.0 i  $N_0$  — węzłem wstępującym równika *CIP* w równik *GCRS* na epokę J2000.0, zaś  $[\Sigma_0 N_0]$  odpowiada kątowi pomiędzy  $\Sigma_0$  — kierunkiem osi  $x$ , czyli początkiem liczenia rektascensji na równiku *GCRS* i  $N_0$ ). Wartość stałej  $s_0$  nie ulega zmianie przy przejściu od modelu precesyjno-nutacyjnego IAU2000 do modelu IAU2006.

Macierz  $Q(t)$  można przedstawić w funkcji współrzędnych  $X, Y$  *CIP* w *GCRS* w postaci

$$Q(t) = \begin{pmatrix} 1 - aX^2 & -aXY & X \\ -aXY & 1 - aY^2 & Y \\ -X & -Y & 1 - a(X^2 + Y^2) \end{pmatrix} R_3(s) \quad (33)$$

gdzie  $a = 1/(1 + \cos d)$  lub z dokładnością  $1 \mu\text{as}$   $a = \frac{1}{2} + \frac{1}{8}(X^2 + Y^2)$ .

Współrzędne  $X, Y$   $CIP$  w  $GCRS$  oparte na modelu precesyjno–nutacyjnym IAU2006 są obliczane ze wzorów:

$$\begin{aligned} X = & -0''.016\,617 + 2004''.191\,898\,t - 0''.429\,782\,9\,t^2 - 0''.198\,618\,34\,t^3 + 0''.000\,007\,578\,t^4 + 0''.000\,005\,928\,5\,t^5 \\ & + \sum_{i,k} [(A_{ls})_{i,k} \sin(ARG) t^k + (A'_{ls})_{i,k} \cos(ARG) t^k] \\ & + \sum_{i,k} [(A_{pl})_{i,k} \sin(ARG) t^k + (A'_{pl})_{i,k} \cos(ARG) t^k] \end{aligned} \quad (34)$$

$$\begin{aligned} Y = & -0''.006\,951 - 0''.025\,896\,t - 22''.407\,274\,7\,t^2 + 0''.001\,900\,59\,t^3 + 0''.001\,112\,526\,t^4 + 0''.000\,000\,135\,8\,t^5 \\ & + \sum_{i,k} [(B_{ls})_{i,k} \sin(ARG) t^k + (B'_{ls})_{i,k} \cos(ARG) t^k] \\ & + \sum_{i,k} [(B_{pl})_{i,k} \sin(ARG) t^k + (B'_{pl})_{i,k} \cos(ARG) t^k] \end{aligned} \quad (35)$$

gdzie parametr  $t$  jest określony wzorem (20), a  $ARG$  jest funkcją fundamentalnych argumentów teorii nutacji (argumenty Delauneya). Dla nutacji księżycowo–słonecznej ( $ls$ )  $ARG$  jest funkcją liniową 5 zmiennych: średniej anomalii Księżyca  $l$ , średniej anomalii Słońca  $l'$ , średniej długości Księżyca pomniejszonej o średnią długość węzła wstępującego Księżyca  $F$ , średniej elongacji Księżyca ze Słońca  $D$  i średniej długości węzła wstępującego Księżyca  $\Omega$ . Dla nutacji planetarnej ( $pl$ )  $ARG$  jest funkcją liniową 14 zmiennych, w skład których obok wyżej wymienionych wchodzi dodatkowo długości 8 planet: Merkurego, Wenus, Ziemi, Marsa, Jowisza, Saturna, Urana i Neptuna, a także całkowita precesja w długości. Współczynniki szeregów dla obliczenia współrzędnych  $X$  i  $Y$  są dostępne na stronie internetowej IERS Convention Centre na <ftp://maia.usno.navy.mil/conv2000/chapter5/>. Do dnia wydania Rocznika na stronach IERS były dostępne współczynniki rozwinięć tylko dla modelu precesyjno–nutacyjnego IAU2000.

Na podstawie porównań z obserwacjami VLBI, dokładność współrzędnych  $X, Y$  otrzymywanych z modelu IAU2000 jest szacowana na około  $0.2\,mas$ . Międzynarodowa Służba Ruchu Obrotowego Ziemi i Systemów Odniesienia (IERS) publikuje więc na bieżąco, wynikające z obserwacji, poprawki  $\delta X, \delta Y$  (dane EOP C04 dostępne na stronach internetowych IERS (<ftp://ftp.iers.org/products/eop/long-term/>)). Poprawki te zawierają m.in. nieuwzględniany w modelu precesyjno–nutacyjnym wpływ tzw. nutacji swobodnej jądra Ziemi. Do dnia wydania Rocznika publikowane przez IERS poprawki odnosiły się do modelu IAU2000A.

Położenie bieguna  $CIP$ , uwzględniające poprawki  $\delta X, \delta Y$  wyraża się wzorami:

$$\tilde{X} = X + \delta X, \quad \tilde{Y} = Y + \delta Y \quad (36)$$

co jest równoważne zastąpieniu macierzy precesyjno–nutacyjnej  $Q$  przez macierz obrotu  $\tilde{Q}$

$$\tilde{Q} = \begin{pmatrix} 1 & 0 & \delta X \\ 0 & 1 & \delta Y \\ -\delta X & -\delta Y & 1 \end{pmatrix} Q \quad (37)$$

Przy dokładnych obliczeniach miejsc pozornych obiektów niebieskich należy uwzględniać poprawki relatywistyczne z tytułu opóźnienia propagacji światła w polu grawitacyjnym Słońca oraz z tytułu grawitacyjnego zakrzywienia światła. Oznaczając przez  $\mathbf{E}_B, \mathbf{Q}_B$  i  $\mathbf{S}_B$  barycentryczne wektory wodzące ( $ICRS$ ), odpowiednio Ziemi ( $E$ ), obiektu niebieskiego ( $Q$ ) i Słońca ( $S$ ), heliocentryczne wektory wodzące Ziemi i obiektu  $Q$  można zapisać jako

$$\mathbf{E} = \mathbf{E}_B(t) - \mathbf{S}_B(t) \quad \mathbf{Q} = \mathbf{Q}_B(t - \Delta t_{lt}) - \mathbf{S}_B(t - \Delta t_{lt}) \quad (38)$$

zaś geocentryczny wektor wodzący obiektu  $Q$  ma postać

$$\mathbf{P} = \mathbf{Q}_B(t - \Delta t_{lt}) - \mathbf{E}_B(t) \quad (39)$$

gdzie  $\Delta t_{lt}$  jest poprawką do czasu z tytułu czasu propagacji światła (light time). Poprawkę tę oblicza się ze wzoru

$$\Delta t_{lt} = \frac{P}{c} + \frac{2GM_S}{c^3} \ln \frac{(E + P + Q)}{(E - P + Q)} \quad (40)$$

gdzie  $E = |\mathbf{E}|$ ,  $Q = |\mathbf{Q}|$  oraz  $P = |\mathbf{P}|$ ,  $c$  jest prędkością światła, a  $GM_S$  — heliocentryczną stałą grawitacyjną. Poprawkę tę można obliczyć z mniejszą dokładnością z uproszczonego wzoru

$$\Delta t_{lt} = \frac{R}{\pi c} \quad (41)$$

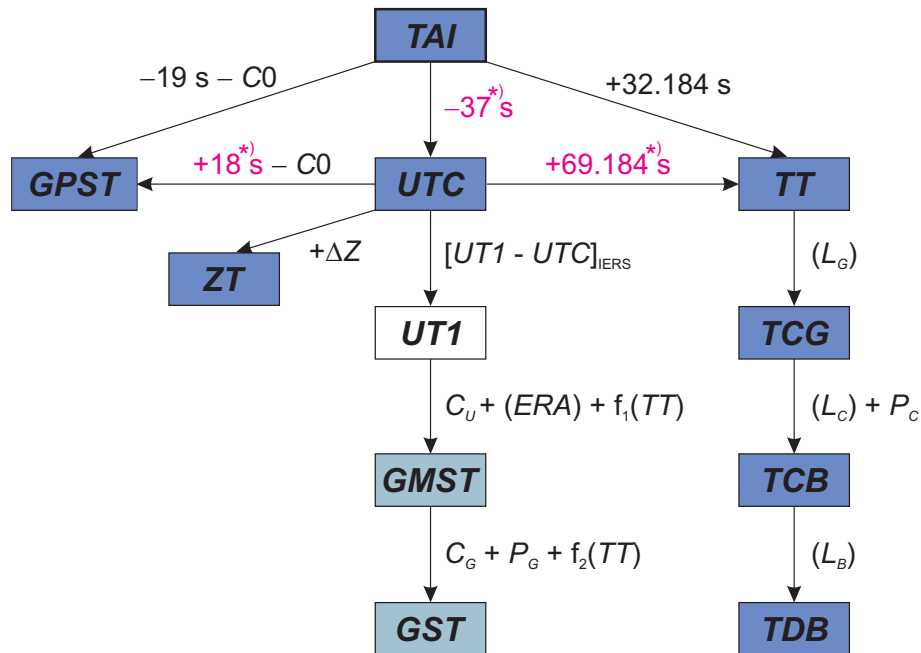

gdzie  $R$  — oznacza promień orbity Ziemi (przybliżenie  $P$ ), a  $\pi$  — paralaksę roczną obiektu  $Q$ .

Oznaczając przez  $\mathbf{e}^E$ ,  $\mathbf{e}^Q$  i  $\mathbf{e}^P$  odpowiednio wektory jednostkowe o kierunkach wektorów  $\mathbf{E}$ ,  $\mathbf{Q}$  i  $\mathbf{P}$ , tj.  $\mathbf{e}^E = \mathbf{E}/E$ ,  $\mathbf{e}^Q = \mathbf{Q}/Q$  i  $\mathbf{e}^P = \mathbf{P}/P$ , efekt grawitacyjnego zakrzywienia światła wyraża się w postaci poprawki  $\Delta \mathbf{e}^P$  do geocentrycznego wektora jednostkowego  $\mathbf{e}^P$  obiektu  $Q$  następująco:

$$\Delta \mathbf{e}^P = \frac{2 GM_S}{c^2 E} \cdot \frac{(\mathbf{e}^P \cdot \mathbf{e}^Q) \mathbf{e}^E - (\mathbf{e}^E \cdot \mathbf{e}^P) \mathbf{e}^Q}{1 + (\mathbf{e}^E \cdot \mathbf{e}^Q)} \quad (42)$$

## 2. SYSTEMY CZASU

Do praktycznego pomiaru czasu są wykorzystywane zjawiska przebiegające okresowo. Odstępy czasu są wyrażane liczbą zawartych w nich okresów przyjętego za wzorzec czasu zjawiska. Do połowy XX wieku podstawą pomiaru czasu był ruch obrotowy Ziemi. Czas astronomiczny oparty o ruch obrotowy Ziemi nosi nazwę **czasu obrotowego**. Szczególnymi rodzajami czasu obrotowego są czas słoneczny, dla którego „zegarem” jest ruch obrotowy Ziemi względem Słońca, odmierzany kątem godzinnym Słońca oraz czas gwiazdowy, dla którego „zegarem” jest ruch obrotowy Ziemi względem punktu równonocy wiosennej, odmierzany kątem godzinnym punktu równonocy wiosennej. W zadanym momencie czas obrotowy w dwóch różnych punktach na powierzchni Ziemi jest różny — z wyjątkiem sytuacji gdy punkty te leżą na tym samym południku geograficznym<sup>7)</sup>. Różnica czasu obrotowego w dwóch punktach na Ziemi odpowiada różnicy długości geograficznej tych punktów. Za podstawową jednostkę czasu obrotowego przyjęto sekundę średniego czasu słonecznego, zdefiniowaną jako 1/86 400 część średniej doby słonecznej. Skala czasu obrotowego jest niejednostajna. W 1954 roku X Generalna Konferencja Wagi i Miar (Conférence Générale des Poids et Mesures) zdefiniowała jako podstawę pomiaru czasu bardziej jednostajną astronomiczną skalę czasu — **czasu newtonowskiego** (czasu fizycznego) opartego na ruchu orbitalnym Ziemi wokół Słońca. Ruch orbitalny Ziemi został opisany w Tablicach Słońca Newcomba, które zawierają model matematyczny pozornego ruchu Słońca na epokę 1900.0, opracowany na podstawie obserwacji astronomicznych z XVIII i XIX wieku. Czas ten nazwano Czasem Efemeryd ( $ET$ ) i za jego jednostkę wynikającą z długości okresu obiegu Ziemi wokół Słońca na epokę 1900.0 przyjęto tzw. sekundę efemerydalną. Definicja ta została ratyfikowana przez XI Generalną Konferencję Wagi i Miar w 1960 roku.

Rys. 2 Współcześnie stosowane skale czasu i ich wzajemne relacje

\*) Wartości obowiązujące w okresie od 1 stycznia 2017 do co najmniej 31 grudnia 2021.

<sup>7)</sup> Przez pojęcie południka geograficznego, długości oraz szerokości geograficznej rozumie się południk astronomiczny oraz odpowiednie współrzędne astronomiczne — w odróżnieniu od południka geodezyjnego oraz długości i szerokości geodezyjnej.

Jednostka czasu oparta na wzorcu astronomicznym wkrótce przestała zadowalać rosnące potrzeby fizyki i techniki. Wzorcem doskonalszym od astronomicznego, pod względem jednostajności skali czasowej, okazał się wzorec atomowy. W 1971 roku za podstawę pomiaru czasu na Ziemi przyjęto zdefiniowaną na 59. sesji Międzynarodowego Komitetu Miar (1970) i zaaprobowaną przez XIV Generalną Konferencję Wąg i Miar (1971) skalę Międzynarodowego Czasu Atomowego (*TAI*).

**Międzynarodowy Czas Atomowy** (*TAI* lub *IAT*) (*Temps Atomique International* lub *International Atomic Time*) jako najbardziej jednostajny stanowi podstawę współczesnych skal czasu. *TAI* jest czasem opartym na wzorcu atomowym (nie związanym z ruchem Ziemi) i jest odmierzany przez zsynchronizowane zegary atomowe rozmieszczone w laboratoriach na całym świecie. Skala czasu *TAI* jest wypadkową wskazań tych zegarów. Wzorce atomowe wykorzystują zjawisko przejść kwantowych między poziomami energetycznymi atomów lub cząsteczek. Uchwała XIII Generalnej Konferencji Wąg i Miar z 1967 roku zdefiniowała sekundę czasu atomowego i uznała ją za podstawową jednostkę czasu w międzynarodowym systemie jednostek SI. Na mocy definicji jest ona „trwaniem 9 192 631 770 okresów odpowiadających rezonansowej częstotliwości przejścia pomiędzy dwoma nadsubtelnymi ( $F=4$ ,  $M=0$ ) i ( $F=3$ ,  $M=0$ ) poziomami stanu podstawowego  $2S\frac{1}{2}$  atomu cezu 133”. Interwał czasu odpowiadający tak zdefiniowanej sekundzie czasu atomowego jest równy sekundzie efemerydalnej. Czas atomowy został zatem wyskalowany do związanego z epoką 1900.0 czasu astronomicznego efemerydalnego.

Niezależne od *TAI* skale czasu atomowego są tworzone dla potrzeb systemów globalnej nawigacji satelitarnej. Wśród nich najpowszechniej używaną jest skala czasu GPS.

**Czas GPS** (*GPST*) (*GPS Time*) jest czasem atomowym używanym w systemie globalnej nawigacji satelitarnej GPS. Podstawą skali czasu GPS są atomowe zegary pokładowe umieszczone na satelitach GPS, zegary atomowe znajdujące się w ośrodkach sterowania systemem GPS oraz zegary atomowe US Naval Observatory. Skala czasu GPS jest bardzo zbliżona do skali czasu *TAI* i zsynchronizowana ze skalą *UTC* na epokę 1980 styczeń 6<sup>d</sup> 0<sup>h</sup> *UTC*. Związek pomiędzy Międzynarodowym Czasem Atomowym a czasem GPS jest następujący:

$$TAI - GPST = 19^s + C0 \quad (43)$$

gdzie 19 s jest stałą różnicą między *TAI* i *UTC* na epokę 1980 styczeń 6<sup>d</sup> 0<sup>h</sup> *UTC*, a *C0* zmienną w czasie poprawką rzędu 10 ns wynikającą z korzystania w obu systemach z różnych zegarów atomowych.

Błędy realizowania skali czasu *TAI* wynikające z niedoskonałości zegarów atomowych nie zawsze są zaniedbywalne. Uznano zatem za konieczne zdefiniowanie idealnej formy *TAI*, którą po uwzględnieniu przesunięcia 32.184 s realizuje tzw. Czas Ziemi (*TT*).

**Czas Ziemi** (*TT*) (*Terrestrial Time* lub *Temps Terrestre*) został zatwierdzony przez XXI Zgromadzenie Generalne IAU (Buenos Aires, 1991) (Rezolucja A4) jako skala czasu przeznaczona do praktycznego odmierzania czasu na Ziemi, w szczególności jako czas odniesienia dla pozornych, geocentrycznych efemeryd (czas ziemski praktycznie wprowadzony był w 1976 roku jako Ziemiński Czas Dynamiczny (*TDT*), który z dniem 1 stycznia 1977 roku zastąpił Czas Efemeryd (*ET*)). *TT* jest zdefiniowany jako skala czasu różniąca się od skali czasu współrzędnych geocentrycznych *TCG* o współczynnik  $L_G$  będący funkcją potencjału siły ciężkości na geoidzie. Z uwagi na niedostateczną dokładność wyznaczenia potencjału siły ciężkości na geoidzie oraz zmienność w czasie pola siły ciężkości Ziemi XXIV Zgromadzenie Generalne IAU (Manchester, 2000) (Rezolucja B1.9) przyjęło stałą wartość współczynnika  $L_G$ , określoną na podstawie ustalonej wartości potencjału siły ciężkości, i uznało ją za jedną ze stałych definiujących obowiązujące systemy astronomiczne i geodezyjne.

Związek pomiędzy Międzynarodowym Czasem Atomowym, a Czasem Ziemi jest następujący:

$$TT - TAI = 32^s.184 \quad (44)$$

zaś relację pomiędzy Czasem Ziemi, a czasem współrzędnych geocentrycznych wyraża wzór

$$TCG - TT = L_G \times (JD - 2443144.5) \times 86400 \quad (45)$$

gdzie

$$L_G = 6.969290134 \times 10^{-10} \quad (46)$$

Wzór (45) gwarantuje zgodność jednostki pomiaru *TT* z sekundą SI na bardzo bliskiej geoidzie powierzchni ustalonego potencjału siły ciężkości.

**Czas współrzędnych geocentrycznych (TCG)** (*Temps Coordonnée Géocentrique* lub *Geocentric Coordinate Time*), wprowadzony przez XXI Zgromadzenie Generalne IAU (Buenos Aires, 1991) (Rezolucja A4), jest czasem w czterowymiarowej czasoprzestrzeni — Niebieskim Geocentrycznym Systemie Odniesienia (*GCRS*) (*Geocentric Celestial Reference System*), który porusza się w przestrzeni wraz z ruchem orbitalnym Ziemi wokół barycentrum Układu Słonecznego, przy czym kierunek osi tego systemu pozostaje niezmienny w odniesieniu do systemu inercjalnego (praktycznie *BCRS*). Czas ten należy do zdefiniowanej w Rezolucji B1.5 XXIV Zgromadzenia Generalnego IAU (Manchester, 2000) metryki relatywistycznej *GCRS*. W tej samej rezolucji znajduje się definicja Niebieskiego Barycentrycznego Systemu Odniesienia (*BCRS*) oraz związanego z nim czasu współrzędnych barycentrycznych.

**Czas współrzędnych barycentrycznych (TCB)** (*Temps Coordonnée Barycentrique* lub *Barycentric Coordinate Time*) jest czasem współrzędnych czterowymiarowego Niebieskiego Barycentrycznego Systemu Odniesienia (*BCRS*) (*Barycentric Celestial Reference System*), który jest traktowany jako system quasi-inercjalny. Czas ten należy do metryki relatywistycznej niebieskiego systemu barycentrycznego. Zależność pomiędzy *TCB* i *TCG* jest wyrażona za pomocą pełnej 4-wymiarowej transformacji Lorentza (Rezolucja B1.5). W przybliżeniu (z dokładnością  $10^{-14}$ ) można używać wyrażenia

$$TCB - TCG = L_C \times (JD - 2\,443\,144.5) \times 86\,400 + c^{-2} \mathbf{v}_e(\mathbf{x} - \mathbf{x}_e) + P \quad (47)$$

gdzie

$$L_C = 1.480\,826\,867\,41 \times 10^{-8} \pm 2 \times 10^{-17} \quad (48)$$

zaś  $\mathbf{x}_e$  i  $\mathbf{v}_e$  oznaczają wektory barycentrycznej pozycji i prędkości środka mas Ziemi,  $\mathbf{x}$  jest wektorem barycentrycznej pozycji obserwatora, a  $P$  przedstawia wyrazy okresowe, których łączna amplituda nie przekracza  $1.6\text{ ms}$  (Rezolucja B1.6).

XVI Zgromadzenie Generalne IAU (Grenoble, 1976) wprowadziło, obok skali Ziemskiego Czasu Dynamicznego *TDT* również skalę czasu dynamicznego odniesionego do barycentrum Układu Słonecznego. Czas ten nazwano Barycentrycznym Czasem Dynamicznym.

**Barycentryczny Czas Dynamiczny (TDB)** (*Temps Dynamique Barycentrique* lub *Barycentric Dynamical Time*) jest czasem atomowym używanym od 1984 roku jako argument efemeryd, np. Księżyca, planet, odniesionych do barycentrum Układu Słonecznego, a także jako argument precesji. *TDB* może być określony jako argument w algorytmach efemerydalnych DE405/LE405 opracowanych przez JPL (efemerydy planetarne zazwyczaj są wyrażane w funkcji czasu  $T_{eph}$ , który jest bardzo zbliżony do *TDB*). *TDB* różni się od *TDT* o wyrazy okresowe spowodowane ruchem orbitalnym Ziemi w polu grawitacyjnym Słońca, Księżyca i planet. Różnica ta, zawierająca efekty relatywistyczne, nie przekracza  $2\text{ ms}$ .

Uznając potrzebę zachowania spójności ze skalą czasu  $T_{eph}$ , XXVI Zgromadzenie Generalne IAU (Praga, 2006) (Rezolucja 3) wprowadziło nową definicję *TDB* opartą na *TCB*

$$TDB = TCB - L_B \times (JD_{TCB} - T_0) \times 86\,400 + TDB_0 \quad (49)$$

gdzie

$$L_B = 1.550\,519\,768 \times 10^{-8} \quad T_0 = 2\,443\,144.500\,372\,5 \quad TDB_0 = -6.55 \times 10^{-5} \quad (50)$$

są stałymi definiującymi <sup>8)</sup>.

Wzorce atomowe nie dostarczają żadnych charakterystycznych momentów, jakie dawałyby możliwość stworzenia naturalnej skali czasu atomowego. Początek skali czasu atomowego musi być obrany umownie przez nawiązanie do skali o trwałej ciągłości. Aspekt chronologiczny metrologii czasu wymaga zegara wzorcowego, który gwarantowałby pomiary bardzo wielkich interwałów czasu i zapewniał skalę dla zdarzeń bardzo odległych w przeszłości i w przyszłości. Naturalnymi skalami czasu są skala czasu astronomicznego. W szczególności, naturalną skalą czasu jest skala czasu obrotowego słonecznego, do której odnoszą się pojęcia dnia i nocy i z którą wiąże się cykl biologiczny żywych organizmów na Ziemi. W skali czasu słonecznego są wyrażane nie wymagające wysokiej precyzji efemerydy ciał niebieskich.

<sup>8)</sup> W Rezolucji B2 ZG IAU 2009 wielkość  $T_0$  nie została zaliczona do stałych definiujących.

**Czas słoneczny** (*Solar Time*) jest definiowany jako tzw. czas słoneczny prawdziwy lub czas słoneczny średni. Czas słoneczny prawdziwy odmierza się geocentrycznym kątem godzinowym środka tarczy słonecznej, zwiększonym o 12 godzin (modulo  $24^h$ ). Czas słoneczny średni mierzy się kątem godzinnym tzw. Słońca średniego, tj. punktu na równiku o rekta-scensji równej średniej długości ekliptycznej Słońca prawdziwego, również zwiększonym o 12 godzin (modulo  $24^h$ ). Czas słoneczny, jako czas obrotowy, może być czasem miejscowym lub tzw. czasem Greenwich<sup>9)</sup>. Pierwszy jest odmierzany kątem godzinnym odniesionym do południka miejscowego, drugi, odniesionym do południka londyńskiego obserwatorium w Greenwich. Czas słoneczny Greenwich różni się od czasu słonecznego miejscowego o długość geograficzną  $\lambda$  południka miejscowego, która na wschód od Greenwich przybiera wartości dodatnie<sup>10)</sup>

$$\text{czas słoneczny miejscowy} = \text{czas słoneczny Greenwich} + \lambda \quad (51)$$

Czas słoneczny prawdziwy jest to czas jaki daje się bezpośrednio wyznaczyć z obserwacji Słońca. Czas słoneczny średni, jako bardziej zbliżony do jednostajnego, jest stosowany w obliczeniach astronomicznych. Znajduje on również zastosowanie w nawigacji i geodezji.

Zależność między rodzajami czasu słonecznego wyraża się za pomocą tzw. równania czasu

$$\text{czas słoneczny prawdziwy} - \text{czas słoneczny średni} = E \quad (52)$$

gdzie  $E$  jest nazywane równaniem czasu<sup>11)</sup>.

Poczynając od 1 stycznia 1925 roku średni czas słoneczny Greenwich (*Greenwich Mean Time* — *GMT* o początku doby w południe), używany w obliczeniach astronomicznych został zastąpiony tzw. czasem uniwersalnym.

**Czas uniwersalny** (*UT* lub *TU*) (*Universal Time* lub *Temps Universel*) to średni czas słoneczny (odniesiony do ruchu dobowego Słońca średniego) południka geograficznego Greenwich.

W dalszej części objaśnień na stronie 180 zostały przedstawione historyczne odmiany czasu uniwersalnego *UT0*, *UT1* i *UT2*, z których obecnie stosuje się jedynie skalę czasu *UT1*.

Definicję *UT1*, obowiązującą od 2003 roku, przyjęto na mocy Rezolucji B1.8 XXIV Zgromadzenia Generalnego IAU (Manchester, 2000). Zgodnie z tą rezolucją, i po uwzględnieniu zmian terminologicznych wprowadzonych na mocy Rezolucji 2 XXVI Zgromadzenia Generalnego IAU (Praga, 2006), *UT1* jest zdefiniowany jako funkcja liniowa Kąta Obrotu Ziemi (*ERA*, oznaczanego także grecką literą  $\theta$ ), który jest kątem w płaszczyźnie równika *CIP* pomiędzy wektorami jednostkowymi skierowanymi od osi *CIP* do Niebieskiego Pośredniego Punktu Początkowego (*CIO*) i Ziemskiego Pośredniego Punktu Początkowego (*TIO*)

$$\theta(T_u) = 2\pi (0.779\,057\,273\,264\,0 + 1.002\,737\,811\,911\,354\,48\,T_u) \quad (53)$$

gdzie  $T_u$  w funkcji *UT1* dane jest wzorem (28), zaś *UT1* jest otrzymywane, zgodnie ze wzorem (29), poprzez dodanie do *UTC* wyznaczanej przez IERS poprawki  $[UT1 - UTC]_{\text{IERS}}$ .

Definicja *UT1* (wzór (53)) zapewnia ciągłość tej skali czasu. Zawarta w niej liniowa zależność *UT1* od Kąta Obrotu Ziemi (*ERA*) świadczy o tym, że *UT1* można interpretować jako miarę rzeczywistego ruchu obrotowego Ziemi wokół *CIP* (nie jak w poprzednio stosowanej definicji wokół chwilowego bieguna lub bieguna *CEP*) względem średniego Słońca. Pochodna *UT1* względem czasu jest proporcjonalna do prędkości kątowej obrotu Ziemi  $\omega$ .

Utrzymywanie skal dokładnego czasu i udostępnianie ich użytkownikom leży w gestii powołanej w tym celu służby czasu. Służba czasu polegała na wyznaczaniu czasu w oparciu o obserwacje gwiazd oraz na kontroli poprawek i niejednostajności wzorców czasu. Odpowiednią do tego celu skalą czasu jest astronomiczna skala gwiazdowego czasu obrotowego. Czas gwiazdowy służył również do określania relacji pomiędzy ziemskim układem odniesienia i niebieskim układem odniesienia.

<sup>9)</sup> Na Konferencji Międzynarodowej w Washington D.C. w 1884 roku południk przechodzący przez obserwatorium w Greenwich został przyjęty jako południk zerowy dla odliczania długości geograficznej, a także dla odliczania czasu.

<sup>10)</sup> Wg uchwały IAU (Patras, 1982), Rezolucja C4.

<sup>11)</sup> Równanie czasu jest funkcją o wartościach oscylujących w okresie roku pomiędzy  $-15$  a  $+17$  minut.

**Czas gwiazdowy** (*Sidereal Time*) może być prawdziwy ( $s_v$ ), quasi-prawdziwy ( $s_q$ ), lub średni ( $s$ ), podobnie jak punkt równonocy wiosennej, którego ruch go definiuje. Odpowiednio więc prawdziwy punkt równonocy wiosennej jest to punkt przecięcia się na sferze niebieskiej ekliptyki z prawdziwym równikiem, tj. z równikiem, którego położenie zależy od precesji i nutacji (w długości). Stosowane do 2003 roku modele nutacji pozwalały wyróżniać nutację długo- ( $\Delta\Psi$ ) i krótkookresową ( $d\Psi$ ) w długości. Istniało zatem pojęcie quasi-prawdziwego punktu równonocy wiosennej. Był to punkt przecięcia na sferze niebieskiej ekliptyki z tzw. quasi-prawdziwym równikiem, którego położenie zależało od precesji i nutacji długookresowej (nie zależało od nutacji krótkookresowej). Średni punkt równonocy wiosennej jest to punkt przecięcia na sferze niebieskiej ekliptyki z tzw. średnim równikiem, tj. równikiem, którego położenie w przestrzeni podlega zmianom tylko pod wpływem precesji księżycowo-słonecznej. Czas gwiazdowy prawdziwy jest to czas jaki daje się bezpośrednio wyznaczyć z obserwacji gwiazd. Czas gwiazdowy średni, jako bardziej zbliżony do jednostajnego, jest stosowany w obliczeniach astronomicznych.

Zależności między rodzajami czasu gwiazdowego były przedstawiane za pomocą następujących wzorów:

$$\begin{aligned}s_q &= s + \Delta\Psi \cos \varepsilon \\ s_v &= s + (\Delta\Psi + d\Psi) \cos \varepsilon\end{aligned}\tag{54}$$

gdzie  $\varepsilon$  oznacza nachylenie ekliptyki do równika, a  $\Delta\Psi \cos \varepsilon$  i  $d\Psi \cos \varepsilon$  przedstawiają długo- i krótkookresową nutację punktu równonocy wiosennej na równiku (w rektascensji).

Podobnie jak w przypadku czasu słonecznego czas gwiazdowy Greenwich różni się od czasu gwiazdowego miejscowego o długość geograficzną  $\lambda$  południka miejscowego, która na wschód od Greenwich przybiera wartości dodatnie

$$\text{czas gwiazdowy miejscowy} = \text{czas gwiazdowy Greenwich} + \lambda\tag{55}$$

Do 2003 roku średni czas gwiazdowy Greenwich był formalnie zdefiniowany jako nieliniowa funkcja *UT1*. Funkcja ta była oparta na wyrażeniu podanym przez Newcomba dla rektascensji średniego Słońca, określającym relację pomiędzy *UT1* a średnim czasem gwiazdowym Greenwich (*GMST*) o  $0^h$  *UT1*. Od 2003 roku średni czas uniwersalny *UT1* jest odniesiony do osi obrotu Ziemi określonej przez Pośredni Biegun Niebieski *CIP*<sup>12)</sup>. Czas *UT1* można więc uważać za kątową miarę rzeczywistego obrotu Ziemi wokół osi *CIP*.

Spójna z nową definicją *UT1* (wzór (53)) jest nowa definicja średniego czasu gwiazdowego Greenwich *GMST*, która w zgodzie z najnowszym, obowiązującym od 1 stycznia 2009 r. modelem precesji P03, przyjmuje postać

$$GMST = 0''.014\,506 + \theta + 4612''.156\,534\,t + 1''.391\,581\,7\,t^2 - 0''.000\,000\,44\,t^3 - 0''.000\,029\,956\,t^4 - 0''.000\,000\,036\,8\,t^5\tag{56}$$

gdzie  $t$  jest dane wzorem (20).

Przyjęty przez IAU, do stosowania od 2003 roku, model precesyjno-nutacyjny IAU2000 nie wyróżnia już nutacji długo- i krótkookresowej. Związek pomiędzy prawdziwym (*GST*) oraz średnim (*GMST*) czasem gwiazdowym Greenwich wyraża się wzorem

$$GST = GMST + Eq\tag{57}$$

przy czym *Eq* jest to równanie równonocy.

Po wprowadzeniu modelu precesyjno-nutacyjnego IAU2000 równanie równonocy opisywane było wzorem

$$Eq = \Delta\psi \cos \varepsilon_A + \sum_k [(C'_{s,0})_k \sin \alpha_k + (C'_{c,0})_k \cos \alpha_k] - 0''.000\,000\,87\,t \sin \Omega\tag{58}$$

gdzie  $\varepsilon_A$  jest nachyleniem ekliptyki poprawionym o zmiany precesyjne zdefiniowane w modelu IAU2000;  $\Delta\psi$  to „całkowita” (bez podziału na składowe długo- i krótkookresową) nutacja w długości odniesiona do ekliptyki zadanej epoki, skąd  $\Delta\psi \cos \varepsilon_A$  jest „klasycznym równaniem równonocy”. Pozostałe dwa człony po prawej stronie (58) stanowią uzupełnienie „równania równonocy”, zapewniające ciągłość prawdziwego czasu gwiazdowego Greenwich po przejściu na nową jego definicję oraz spójność z pozostałymi wielkościami systemu IAU2000. Parametry  $\alpha_k$  i  $\Omega$  oraz wartości współczynników  $(C'_{s,0})_k$  i  $(C'_{c,0})_k$  są podane w IERS Technical Note 32 „*IERS Conventions (2003)*”, a także w wersji elektronicznej wraz z pełną numeryczną reprezentacją *GST* na stronie internetowej <http://maia.usno.navy.mil/ch5tables.html>.

<sup>12)</sup> Biegun *CIP* znajduje się bardzo blisko bieguna chwilowej osi obrotu Ziemi.

Po zastąpieniu modelu IAU2000 nowym modelem precesyjno–nutacyjnym IAU2006 wartość równania równonocy wyznacza się jako różnicę czasu gwiazdowego prawdziwego oraz czasu gwiazdowego średniego

$$Eq = GST - GMST \quad (59)$$

przy czym czas gwiazdowy prawdziwy jest obliczony bezpośrednio, wychodząc od pełnej macierzy precesyjno–nutacyjnej IAU2006 oraz tzw. równania początków (*equation of origins*). Podejście to jest równoważne poprzednio stosowanemu podejściu z użyciem modelu IAU2000.

Rolę jaką odgrywał czas gwiazdowy w transformacji pomiędzy układami ziemskim i niebieskim przejął Kąt Obrótu Ziemi (*ERA*), który nie jest obciążony wpływem precesji i nutacji. W nowym wyrażeniu na *GST* w funkcji czasu kąt  $\theta$  (*ERA*) jest wyrażony w funkcji *UT1*, zaś pozostałe człony reprezentujące efekt precesji i nutacji w rektascensji są odniesione do skali czasu *TDB* (praktycznie do *TT*). Zgodnie z nową definicją *GMST* nie jest już kątem godzinnym średniej równonocy wiosennej na południku Greenwich. Należy zauważyć, że wprowadzanie w przyszłości nowych poprawionych modeli precesyjno–nutacyjnych spowoduje konieczność formułowania nowych wyrażen dla *GMST*. Także „równanie równonocy” nie prowadzi do prawdziwej rektascensji średniej równonocy. Obecna rola czasu gwiazdowego ogranicza się do umożliwienia zachowania ciągłości w obliczeniach astronomicznych. W szczególności  $\theta(J2000.0) = GMST(J2000.0)$ , zaś różnica *GST* —  $\theta$  określa rektascensję *CIO*, a tym samym położenie punktu równonocy wiosennej na równiku *CIP*.

**Dynamiczny Czas Gwiazdowy** (*SDT*) (*Sidereal Dynamical Time*) jest odpowiednikiem *TT* w grupie skal czasu gwiazdowego. Definiuje się go dokładnie tak samo jak średni czas gwiazdowy Greenwich (*GMST*) tyle, że w odniesieniu do skali Czasu Ziemskiego, tj. we wzorze (56) kąt  $\theta$  powinien być obliczony zgodnie z (53), przy czym argument  $T_u = JD(TT) - 2451\,545.0$ . Otrzymany w ten sposób *SDT* jest czasem średnim. Dynamiczny czas gwiazdowy prawdziwy otrzymuje się poprzez dodanie nutacji w rektascensji  $\Delta\psi \cos \varepsilon_A$  do dynamicznego czasu gwiazdowego średniego.

Używana w służbie czasu skala czasu astronomicznego obrotowego jest nie tylko niejednostajna ale z uwagi na spowalnianie prędkości obrotowej Ziemi (rok słoneczny ulega skracaniu w tempie 0.2–1.2 sekundy na rok), spowodowanej efektami pływowymi, wykazuje dodatkowo nieliniowy trend w stosunku do jednostajnej skali czasu atomowego. Wprowadzona w 1964 roku skala Czasu Uniwersalnego Koordynowanego jest bliską aproksymacją niejednostajnego czasu obrotowego uniwersalnego *UT1* skalą czasu atomowego.

**Czas Uniwersalny Koordynowany** (*UTC* lub *TUC*) (potocznie — *Universal Time Coordinated*, poprawnie — *Coordinated Universal Time* lub *Temps Universel Coordonné*), jako najbardziej zbliżony do czasu słonecznego średniego na południku Greenwich, czas przedziałami jednostajny, stanowi od 1964 roku podstawę czasu cywilnego utrzymywanego początkowo przez BIH a następnie od 1988 roku przez Sekcję Czasu BIPM w Paryżu (do 1964 roku czas cywilny opierał się na skali czasu słonecznego średniego Greenwich *GMT* zwanej również czasem uniwersalnym *UT*). Lokalne realizacje *UTC* są prowadzone przez narodowe laboratoria czasu. Pierwotnie utrzymywano skalę czasu koordynowanego w pobliżu aktualnej przeciętnej wartości skali czasu uniwersalnego średniego *UT1* (dopuszczalne odchylenie  $5 \times 10^{-9}$ ), zachowując różnicę obu czasów — w granicach 0.1 sekundy. Zmiany wprowadzano skokami z zastosowaniem zmiennej częstotliwości *UTC*. Od stycznia 1972 roku zaniechano jednak zmian częstotliwości *UTC* i zwiększono tolerancję różnic *UT1* — *UTC*. Wskazania Czasu Uniwersalnego Koordynowanego mogą teraz odbiegać o mniej niż 1 sekundę od *UT1* i różnić się od jednoczesnych wskazań Międzynarodowego Czasu Atomowego (*TAI*) tylko o całkowitą liczbę sekund. Zmiany mające zapobiec większemu niż 1 sekunda oddaleniu czasu koordynowanego od czasu uniwersalnego są dokonywane poprzez dodanie tzw. sekundy przestępnej (leap second) 31 grudnia lub 30 czerwca. Od 1 stycznia 2017 roku różnica ta wynosi<sup>13)</sup>:

$$TAI - UTC = 37^s \quad (60)$$

Różnice [*UT1* — *UTC*], a także [*UT1* — *TAI*], określające relacje pomiędzy skalą czasu astronomicznego obrotowego i skalami czasu atomowego są regularnie wyznaczone przez IERS na podstawie obserwacji VLBI, GPS, SLR i DORIS, a następnie publikowane w biuletynach IERS (<http://www.iers.org>).

<sup>13)</sup> Wprowadzenie sekundy przestępnej jest każdorazowo ogłaszane w wydawanym przez IERS biuletynie C; (<ftp://hpiers.obspm.fr/eop-pc/bul/bulc/>).

Kierując się względami praktycznymi, związanymi z posługiwaniem się czasem w życiu codziennym, na Konferencji Międzynarodowej w Washington D.C. w 1884 roku wprowadzono czas strefowy. Dokonano w tym celu podziału Ziemi na 24 południkowe strefy godzinne, każda o szerokości  $15^\circ$ . Granice stref dostosowano do wygody i życzenia mieszkańców poszczególnych regionów (w USA określono je dopiero w 1918 roku). Wewnątrz strefy obowiązuje jednolity czas strefowy. Południki strefowe przebiegające przez środek stref czasowych:  $0^\circ$ ,  $15^\circ$ ,  $30^\circ$ , ..., w kierunku na wschód od Greenwich ponumerowano odpowiednio liczbami całkowitymi: 0, 1, 2, ..., przypisując każdemu południkowi strefowemu odpowiednią liczbę  $\Delta Z$ .

**Czas strefowy (ZT) (Zonal Time)** jest to czas koordynowany (atomowy) południków strefowych. ZT jest przesunięty względem UTC (do 1964 roku względem czasu astronomicznego obrotowego GMT lub UT) o całkowitą (w większości wypadków) liczbę  $\Delta Z$  godzin, tj.:

$$ZT = UTC + \Delta Z \quad (61)$$

Poszczególne kraje opierają rachubę swego czasu urzędowego przeważnie na najbliższym południku strefowym. W Polsce podstawowym czasem urzędowym jest czas środkowoeuropejski (CSE), czyli czas południka oddalonego o  $15^\circ$  na wschód od Greenwich (jest to w przybliżeniu południk Zgorzelca). W innych państwach ustalony czas urzędowy obowiązuje nierzadko na obszarze kilku stref czasowych lub bywa przesunięty od odpowiedniego czasu strefowego o 30 lub 15 minut. W niektórych krajach w okresie letnim jest wprowadzany tzw. czas letni. Przy przechodzeniu z czasu zimowego na letni wskazówki zegarów są przesuwane o 1 godzinę do przodu, a przy powrocie na czas zimowy są o 1 godzinę cofane. W Polsce czas letni (czyli czas wschodnioeuropejski — czas południka  $30^\circ\text{E}$ ) obowiązywał od wiosny do jesieni w latach 1946–1949 i 1957–1964, a począwszy od 1977 roku jest wprowadzany corocznie. Relacja między letnim i zimowym czasem urzędowym w Polsce a Czasem Uniwersalnym Koordynowanym przedstawia się następująco:

$$\text{czas letni} = \text{czas wschodnioeuropejski} = UTC + 2^h$$

$$\text{czas zimowy} = \text{czas środkowoeuropejski (CSE)} = UTC + 1^h$$

W zagadnieniach, w których nie jest wymagana lepsza od 1 sekundy dokładność rejestracji czasu, czas środkowoeuropejski koordynowany można utożsamiać ze średnim słonecznym czasem środkowoeuropejskim. W przypadkach jednak, w których są wyższe wymagania dokładności rejestracji czasu, np. przy precyzyjnych wyznaczeniach astronomicznych azymutu, należy rozróżnić skalę czasu koordynowanego (atomowego) od skali czasu obrotowego.

W przeszłości istotną rolę odgrywały także inne, niestosowane obecnie, skale czasów. Do końca lat 30. XX wieku czas uniwersalny UT był uważany za jednostajną skalę czasu. Nieregularności UT dostrzeżono dopiero dzięki zastosowaniu zegarów kwarcowych, a później zegarów atomowych. Na podstawie analizy źródeł tych nieregularności, w miejsce czasu UT wprowadzono trzy jego reprezentacje, przy czym pojęcie czasu UT pozostawało nadal w użyciu przy określaniu czasu uniwersalnego gdy nie była wymagana wysoka dokładność:

*UT0* (lub *TU0*) — czas uniwersalny prawdziwy — wyznaczany bezpośrednio (po uwzględnieniu równania czasu) z obserwacji astronomicznych średni czas słoneczny średniego południka Greenwich, od którego były odmierzane długości geograficzne. Płaszczyzna średniego południka Greenwich była określona przez dwa kierunki: kierunek linii pionu w Greenwich oraz kierunek równoległy do średniej osi obrotu Ziemi<sup>14)</sup>, która łączy średnie bieguny geograficzne. Prawdziwy czas uniwersalny można było uważać za kątową miarę rzeczywistego obrotu Ziemi wokół średniej osi obrotu.

*UT1* (lub *TU1*) — czas uniwersalny średni — średni czas słoneczny chwilowego południka Greenwich, odniesionego do chwilowej osi obrotu Ziemi<sup>15)</sup> (czas uniwersalny średni, w którym zostały uwzględnione okresowe zmiany wywołane strefową składową pływów oznaczano przez *UT1R* — okresowości 5 – 35 dób, *UT1S* — okresowości 5 dób – 18.6 lat oraz *UT1D* — okresowości dobowe i krótsze: IERS Technical Note 21, 1996). Średni czas uniwersalny można było uważać za kątową miarę rzeczywistego obrotu Ziemi wokół chwilowej osi obrotu, która łączy chwilowe bieguny geograficzne.

<sup>14)</sup> W latach 1967–1988 średnia oś obrotu Ziemi była określona przez międzynarodowy umowny średni biegun północny Ziemi CIO\*. Obecnie jest ona określona przez biegun ITRS.

<sup>15)</sup> W latach 1988–2002 oś chwilowa była utożsamiana z osią bieguna CEP, od roku 2003 — z osią bieguna CIP.

### Zestawienie okresów, w których obowiązywał w Polsce czas letni

Dane począwszy od 2017 roku: Rozp. Prezesa Rady Ministrów z 3 listopada 2016 r. w sprawie wprowadzenia i odwołania czasu letniego środkowoeuropejskiego w latach 2017–2021, Dz. U. z dnia 14 listopada 2016 r., poz. 1833.

*UT2* (lub *TU2*) — czas uniwersalny quasi-jednostajny — średni czas słoneczny chwilowego południka Greenwich uwolniony od sezonowych nieregularności ruchu obrotowego Ziemi. Quasi-jednostajny czas uniwersalny można było uważać za kątową miarę „uśrednionego” obrotu Ziemi wokół chwilowej osi obrotu<sup>16)</sup>.

Podane definicje reprezentacji systemów czasu uniwersalnego obowiązywały do 2003 roku. Zależności między zdefiniowanymi powyżej systemami czasu uniwersalnego można przedstawić za pomocą następujących wzorów:

$$UT1 = UT0 + \Delta\lambda \quad (62)$$

$$UT2 = UT0 + \Delta\lambda + \Delta T_s = UT1 + \Delta T_s \quad (63)$$

Znaczenie poprawek  $\Delta\lambda$  i  $\Delta T_s$ , które reprezentują odpowiednio efekt ruchu bieguna oraz sezonowe nieregularności ruchu obrotowego Ziemi zdefiniowano w części szczegółowej objaśnień RA (patrz wzory (75) i (76)).

Czasem astronomicznym bardziej jednostajnym od czasu obrotowego był Czas Efemeryd.

**Czas Efemeryd** (*ET* lub *TE*) (*Ephemeris Time* lub *Temps des Ephémérides*) zwany również czasem efemerydalnym, wprowadzony w 1954 roku, był czasem słonecznym lecz nie związanym z ruchem obrotowym Ziemi, a z jej ruchem orbitalnym wokół Słońca. Nieco później definicję *ET* związano również z ruchem orbitalnym Księżyca wokół Ziemi. Nie istnieje

<sup>16)</sup> W latach 1988–2002 oś chwilowa była utożsamiana z osią bieguna *CEP*, od roku 2003 — z osią bieguna *CIP*.

wzorzec podstawowy reprodukuje dobę  $ET$ . Miarą Czasu Efemeryd jest pozycja Słońca, a dokładnie jego długość ekliptyczna. Sekundę Czasu Efemeryd, która do 1967 roku była podstawową jednostką czasu, określa się jako  $1/31\,556\,925.974\,7$  część roku zwrotnikowego<sup>17)</sup> epoki 1900 styczeń  $0^d\,12^h$  Czasu Efemeryd.

Niestalość jednostek czasów słonecznego i gwiazdowego związanych z ruchem obrotowym Ziemi wynika nie tylko ze zmian sezonowych  $\Delta T_s$  w prędkości kątowej ruchu obrotowego Ziemi ale także z powodu zmian wiekowych i okresowych  $\Delta T$  tego ruchu. Zależność między Czasem Efemeryd a czasem uniwersalnym jest następująca:

$$ET = UT2 + \Delta T \quad (64)$$

gdzie  $\Delta T$  jest poprawką, której dokładną wartość można było otrzymać *ex post*, i to ze znacznym opóźnieniem wynikającym z konieczności opracowania pewnego okresu obserwacji długości ekliptycznej Księżyca i porównaniu z efemerydą. Poprawkę tę otrzymuje się na mocy wzorów:

$$\begin{aligned} \Delta T &= 24.349 + 72.318T + 29.950T^2 + 1.82144B''/1'' \\ B'' &= \lambda_{obs} - [\lambda_{Br.} + 4.65 + 12.96T + 5.22T^2 - 10.71 \sin(240.7 + 140.0T)] \end{aligned} \quad (65)$$

We wzorach (65)  $T$  oznacza liczbę stuleci juliańskich liczonych od momentu 1900 styczeń  $0^d\,12^h\,UT1$ , zaś  $B''$  jest to tzw. fluktuacja, która przedstawia różnicę: zaobserwowana długość ekliptyczna Księżyca ( $\lambda_{obs}$ ) pomniejszona o jej wartość wziętą z tablic Browna ( $\lambda_{Br.}$ ), poprawiona o stałą i uzupełniona wiekowymi i okresowymi przyspieszeniami ruchu Księżyca. Dodać należy, że niejednostajność czasu słonecznego zaznacza się również w ruchu planet wewnętrznych. Ułożone przez Newcomba tablice Słońca z argumentem „czas uniwersalny” pozostają w mocy ze zmianą jedynie nazwy argumentu „czas uniwersalny” na „Czas Efemeryd”.

W roku 2021, zgodnie z przewidywaniami zawartymi w biuletynach IERS, można przyjmować następującą przybliżoną relację między Czasem Efemeryd a czasem uniwersalnym:

$$ET = UT1 + 69^s \quad (66)$$

Wadą Czasu Efemeryd jest jego zależność od podlegającej udoskonaleniom teorii ruchu Księżyca, a także nieuwzględnienie w nim efektów wynikających z ogólnej teorii względności.  $ET$  był używany jako argument równań ruchu ciał niebieskich układu słonecznego do 1984 roku, kiedy to został zastąpiony zdefiniowanym przez XVI Zgromadzenie Generalne IAU (Grenoble, 1976) (Rezolucja 5) Ziemijskim Czasem Dynamicznym.

**Ziemijski Czas Dynamiczny** ( $TDT$ ) (*Temps Dynamique Terrestre* lub *Terrestrial Dynamical Time*) był czasem atomowym odniesionym do środka mas Ziemi i zdefiniowanym następująco:

$$TDT = TAI + 32.184 \quad (67)$$

$TDT$  był używany jako argument efemeryd dla obserwacji z powierzchni Ziemi. Przesunięcie skali czasu  $TDT$  w stosunku do  $TAI$  o 32.184 s, odpowiadające różnicy między  $ET$  i  $TAI$  1977 styczeń  $1^d\,0^h$ , zostało wprowadzone w celu zachowania ciągłości liczenia czasu przy przejściu od  $ET$  do  $TDT$ . Tablice Słońca Newcomba pozostały zatem nadal w mocy ze zmianą nazwy argumentu „Czas Efemeryd” na „Ziemijski Czas Dynamiczny”. Tak jak w przypadku  $ET$ , w roku 2021 można przyjmować przybliżoną relację między Ziemijskim Czasem Dynamicznym a czasem uniwersalnym:

$$TDT = UT1 + 69^s \quad (68)$$

Na mocy Rezolucji 4 XXI Zgromadzenia Generalnego IAU (Buenos Aires, 1991) Ziemijski Czas Dynamiczny został zastąpiony równoważnym mu Czasem Ziemijskim ( $TT$ ), tj.:

$$TT \equiv TDT \quad (69)$$

Astronomiczna rachuba czasu stosowana do długich jego odstępów (lat, stuleci) wiąże się z ruchem orbitalnym Ziemi. Okres pomiędzy dwoma kolejnymi przejściami środka Ziemi przez płaszczyznę utworzoną przez środek Słońca, punkt równonocy wiosennej oraz kierunek bieguna ekliptyki jest nazwany rokiem zwrotnikowym. Zawiera on  $365.242\,198\,79 - 0.000\,006\,14 \times t$  dób, gdzie  $t$  oznacza liczbę stuleci juliańskich od epoki 1900 styczeń  $0^d\,12^h$  Czasu Efemeryd czyli od południa 31 grudnia 1899 r. Interwał czasu odpowiadający  $1/31\,556\,925.974\,7$  części roku zwrotnikowego na tę epokę został przyjęty jako sekunda Czasu Efemeryd, a następnie został uznany jako podstawowa jednostka czasu atomowego i miara sekundy SI.

<sup>17)</sup> Rok zwrotnikowy jest to odstęp czasu pomiędzy dwoma kolejnymi przejściami środka masy Ziemi przez płaszczyznę, którą tworzy środek Słońca, punkt równonocy wiosennej i kierunek bieguna ekliptyki (w ciągu roku zwrotnikowego długość ekliptyczna Słońca zmienia się o  $360^\circ$ ).

Rys. 3 Zależności pomiędzy niektórymi stosowanymi skalami czasu

**Data juliańska ( $JD$ )** (*Julian Date*) jest ciągłą rachubą dni wprowadzoną w XVI wieku. Za początek tzw. okresu juliańskiego, od którego liczy się dni juliańskie, przyjęto moment  $-4712$  styczeń  $1^d 12^h$  czyli południe 1 stycznia 4713 p.n.e. Pierwotnie data juliańska była odniesiona do skali średniego czasu słonecznego, a do niedawna, do 1997 roku do  $UT1$ . Niekiedy specyfikowano daty juliańskie w odniesieniu do Czasu Efemeryd  $ET$  i wówczas oznaczano je jako  $JED$  (*Julian Ephemeris Date*). Doba juliańska zawsze rozpoczyna się o  $12^h 00^m 00^s$ , a jej długość odpowiada 24 godzinom lub 1440 minutom lub 86 400 sekundom skali czasu, do której została odniesiona. I tak, na przykład doba juliańska odniesiona do skali  $UT1$  odpowiada 86 400 sekundom  $UT1$ , czyli średniego czasu słonecznego, zaś doba juliańska odniesiona do  $ET$  odpowiada 86 400 sekundom efemerydalnym. Moment 1900 styczeń  $1^d 12^h UT1$  odpowiada  $JD(UT1) 2\,415\,021.0$ , zaś epoka  $J2000.0$  (2000 styczeń  $1^d 12^h UT1$ ) odpowiada  $JD(UT1) 2\,451\,545.0$ .

XXIII Zgromadzenie Generalne IAU (Kyoto, 1997) na mocy Rezolucji B1 zaleciło aby data juliańska była wyrażana w skali Czasu Ziemi  $TT$ . W przypadku odniesienia daty juliańskiej do innej niż  $TT$  skali czasu, np.  $UT1$ , należy więc w myśl tej rezolucji stosować oznaczenie  $JD(UT1)$ .

Dla skrócenia zapisu i uproszczenia obliczeń, w końcu lat 1950, wprowadzono tzw. zmodyfikowaną datę juliańską ( $MJD$ ) (*Modified Julian Date*). Zazwyczaj korzysta się z następującej definicji  $MJD$ :

$$MJD = JD - 2\,400\,000.5 \quad (70)$$

Początek  $MJD$  pokrywa się z początkiem doby, tj.  $0^h$  odpowiedniej skali czasu. Rok juliański odpowiada 365.25 dobom juliańskim, zaś stulecie juliańskie odpowiada 36 525 dobom juliańskim.

**Juliańska data gwiazdowa ( $JSD$ )** (*Julian Sidereal Date*) zwana również Datą Gwiazdową Greenwich ( $GSD$ ) (*Greenwich Sidereal Date*) jest odpowiednikiem daty juliańskiej, odniesionej do skali czasu gwiazdowego.  $JSD$  jest definiowany jako interwał czasu liczony w dobach gwiazdowych, określonych przez punkt równonocy na daną epokę, jaki upłynął na południku Greenwich od początku doby gwiazdowej, w której wypada moment  $JD 0.0$ . Przykładowo  $JSD 2\,421\,633.0$  odpowiada momentowi 1899 grudzień  $31^d 17^h 21^m 07.2^s UT1$  ( $JD 2\,415\,020.223$ ). Przybliżone zależności pomiędzy rachubami  $JD$  i  $JSD$  wyglądają następująco:

$$\begin{aligned} JSD &= +0.671 + 1.002\,737\,909\,3 \times JD \\ JD &= -0.669 + 0.997\,269\,566\,4 \times JSD \end{aligned}$$

## CZĘŚĆ SZCZEGÓŁOWA

### Czas gwiazdowy Greenwich i Kąt Obrotu Ziemi (str. 8÷11)

Średni czas gwiazdowy Greenwich  $GMST$  o zerowej godzinie czasu uniwersalnego średniego  $UT1$  obliczono w odstępach dobowych według wzoru (56) zatwierdzonego uchwałą Międzynarodowej Unii Astronomicznej (Manchester, 2000) (Rezolucja B1.8). Wzór ten uwzględnia poprawkę związaną z obowiązującym od 2003 roku przejściem od punktu równonocy wiosennej (ekwinokcjum) systemu FK5 do  $CEO$  (obecnie  $CIO$ ) w  $IRS$  oraz przejściem od modelu precesyjno-nutacyjnego IAU2000 do modelu IAU2006 i zapewnia ciągłość w  $UT1$ , wyznaczanym z obserwacji astronomicznych i satelitarnych

$$GMST \text{ o } 0^h UT1 = 2\pi(0.779\,057\,273\,2640 + 1.002\,737\,811\,911\,354\,48T_u) + \\ + 0.014\,506 + 4612.156\,534\,t + 1.391\,581\,7\,t^2 - 0.000\,000\,44\,t^3 - 0.000\,029\,956\,t^4 - 0.000\,000\,036\,8\,t^5 \quad (71)$$

gdzie  $T_u$  jest wyrażony w dobach juliańskich<sup>18)</sup> odniesionych do skali czasu  $UT1$

$$T_u = JD(UT1) - 2\,451\,545.0 \quad (72)$$

zaś parametr  $t$  jest wyrażony w stuleciach juliańskich odniesionych do skali czasu  $TT$

$$t = (JD(TT) - 2000 \text{ styczeń } 1^d 12^h TT) / 36\,525 \quad (73)$$

Argumenty  $UT1$  i  $TT$  we wzorach (72) i (73) wyznacza się w oparciu o  $UTC$  z następujących zależności:

$$UT1 = UTC + [UT1 - UTC]_{\text{IERS}} \\ TT = UTC + 69^s.184$$

gdzie różnica  $[UT1 - UTC]_{\text{IERS}}$  jest wyznaczanym przez IERS parametrem ruchu obrotowego Ziemi<sup>19)</sup>.

Przy obliczaniu prawdziwego czasu gwiazdowego Greenwich  $GST$  stosowano wzory zatwierdzonej uchwałą IAU (Praha, 2006) teorii precesyjno-nutacyjnej IAU2006 (Rezolucja 1).

Wartości równania równonocy  $Eq$  otrzymuje się jako różnicę prawdziwego czasu gwiazdowego  $GST$  i średniego czasu gwiazdowego Greenwich  $GMST$ , zgodnie z zależnością (59).

Kąt Obrotu Ziemi ( $ERA$ )  $\theta$  zgodnie z Rezolucją B1.8 IAU (Manchester, 2000) jest obliczany wg wzoru (27).

#### Przykłady

- 1) Wyrazić moment 2021 lipiec 25<sup>d</sup> 21<sup>h</sup> 45<sup>m</sup> 30.0000 czasu wschodnioeuropejskiego w średnim i prawdziwym czasie gwiazdowym południka Borowej Góry; rachunek należy prowadzić do 0.0001.

| plus równanie równonocy $Eq$               | − 0.8776                                | c)                         |
| prawdziwy czas gwiazdowy BG                | 17 24 34.9531                           |                            |

<sup>18)</sup> Data juliańska na 0<sup>h</sup>  $TT$  każdego dnia roku 2021 jest podana w trzeciej kolumnie w tablicach pozycji Słońca na str. 12÷19.

<sup>19)</sup> Poprawki do czasu uniwersalnego są podane w tablicach na str. 40÷41.

- a)  $19^h 45^m 29.8200^s = 71\,129.8200$ ;  $71\,129.8200 \times 0.002\,737\,909\,3 = 194.7470$  (patrz wzór na str. 165).
- b) Wg uchwały IAU (Patras, 1982) (Rezolucja C4), długości geograficzne na wschód od Greenwich przybierają znak dodatni. Długość geograficzna BG wynosi  $1^h 24^m 08.9140^s$  (str. 7).
- c) Ze str. 10 wypisujemy podane na  $0^h$  czasu  $UT1$  na okalające daty wartości równania równonocy  $Eq$ , a następnie tworzymy różnice

|   |           |           |           |
|---|-----------|-----------|-----------|
| 24  | $-0.8841$ | $+0.0052$ | $-0.0040$ |
| 2021.VII.25 <sup>d</sup> 0 <sup>h</sup> $UT1$ | $-0.8789$ | $+0.0012$ | $-0.0036$ |
| 26  | $-0.8777$ | $-0.0024$ |           |
| 27  | $-0.8801$ |           |           |

Posłużymy się wzorem interpolacyjnym Bessela

$$u = u_0 + n\Delta_{1/2}^I + \frac{n(n-1)}{4} (\Delta_0^{II} + \Delta_1^{II}) + \dots$$

w którym pomijamy wyrazy zawierające trzecie i dalsze różnice, ponieważ nie mają one tu znaczenia praktycznego. Otrzymujemy

|  |  |             |
|--|--|-------------|
|  | $u_0$  | $= -0.8789$ |
| $n = \frac{19^h 45^m 29.8200^s}{24^h} = +0.8233$ | $n\Delta_{1/2}^I$                                  | $= +0.0010$ |
| $\frac{n(n-1)}{4} = -0.0364$                     | $\frac{n(n-1)}{4} (\Delta_0^{II} + \Delta_1^{II})$ | $= +0.0003$ |
|  | $u$  | $= -0.8776$ |

Jeżeli rachunek zamiany czasów prowadzimy do  $0.001$ , to równanie równonocy wystarczy interpolować liniowo, a redukcję czasu średniego słonecznego do czasu średniego gwiazdowego można wykonać korzystając ze wzoru (16).

- 2) Wyrazić moment 2021 lipiec 25<sup>d</sup> 17<sup>h</sup> 24<sup>m</sup> 34.9531 prawdziwego czasu gwiazdowego południka Borowej Góry w czasie środkowoeuropejskim i w czasie wschodnioeuropejskim; rachunek należy prowadzić do  $0.0001$ .

|   |                     |                            |
|---|---------------------|----------------------------|

| $GMST$ w zadanym momencie                                 | $16\,00\,26.9167$   |                            |
| minus $GMST$ o 0 <sup>h</sup> $UT1$                       | $-20\,11\,42.3497$  | ze str. 10                 |
| $\Delta s$ – interwał cz. śr. gw. od 0 <sup>h</sup> $UT1$ | $19\,48\,44.5670$   |                            |
| minus red. int. $\Delta s$ na odp. int. $UT1$             | $3\,14.7470$        | wzór (17) ze str. 165      |
| $UT1$   | $19\,45\,29.8200$   |                            |
| minus poprawka $[UT1 - UTC]_{\text{IERS}}$                | $+ 0.1800$          | ze str. 41 (interpolowane) |
| $UTC$   | $19\,45\,30.0000$   |                            |
| plus redukcja strefowa $\Delta Z$                         | $+ 1\,00\,00.0000$  |                            |
| czas środkowoeuropejski                                   | $20\,45\,30.0000$   |                            |
| plus redukcja strefowa $\Delta Z$                         | $+ 1\,00\,00.0000$  |                            |
| czas wschodnioeuropejski                                  | $21\,45\,30.0000$   |                            |

- a) Równanie równonocy interpolujemy jak w przykładzie poprzednim. Do obliczenia współczynnika  $n$  potrzebna jest znajomość a priori  $UT1$  w zadanym momencie. Jednakże niedokładność rzędu  $0.1^m$  nie stanowi przeszkody, toteż potrzebną wartość czasu  $UT1$  można obliczyć w następujący sposób:

|   |              |                       |
|---|--------------|-----------------------|
| czas gwiazdowy Greenwich                                | $16^h 00.43$ |                       |
| minus czas gwiazdowy Gr. o 0 <sup>h</sup> $UT1$         | $-20\,11.71$ |                       |
| $\Delta s$ – interwał czasu gw. od 0 <sup>h</sup> $UT1$ | $19\,48.72$  |                       |
| minus red. int. $\Delta s$ na odp. int. $UT1$           | $- 3.25$     |                       |
| $UT1$   | $19\,45.47$  | wzór (17) ze str. 165 |

Następnie obliczamy współczynnik interpolacyjny:  $n = \frac{19\,45.48}{24^h} = +0.8232$

Dalej postępujemy jak w przykładzie poprzednim.

Jeżeli obliczenia zamiany czasów są prowadzone do  $0.001$ , to równanie równonocy  $Eq$  wystarczy interpolować liniowo, przy czym do obliczenia współczynnika interpolacyjnego  $n$  zadowalająca jest znajomość czasu uniwersalnego do  $0.1^h$ .

- 3) Obliczyć wartość Kąta Obrotu Ziemi na moment 2021 sierpień 12<sup>d</sup> 7<sup>h</sup> 35<sup>m</sup> 40.0000 czasu środkowoeuropejskiego; rachunek prowadzić do 0.0001.

|   |  |            |
|---|--|------------|
| <i>CSE</i>                                | 7 <sup>h</sup> 35 <sup>m</sup> 40.0000 |            |
| minus redukcja strefowa $\Delta Z$        | -1 00 00.0000                          |            |
| <i>UTC</i>                                | 6 35 40.0000                           |            |
| plus poprawka $[UT1 - UTC]_{\text{IERS}}$ | - 0.1700                               | ze str. 41 |
| <i>UT1</i>                                | 6 35 39.8300                           |            |

Wartość Kąta Obrotu Ziemi można teraz obliczyć korzystając bezpośrednio ze wzoru (27) na str. 172, przyjmując  $T_u = JD(UT1) - J2000.0 = 2\,459\,438.5 + \frac{6\,35\,39.8300}{24^h} - 2\,451\,545.0 = 7\,893.774\,766\,551$  oraz biorąc wartość Kąta Obrotu Ziemi  $\theta$  modulo  $2\pi$  i wyrażając ją w jednostkach czasu

$$\theta = 3^h 58^m 18.7166^s$$

lub za pomocą liniowej interpolacji wartości  $\theta$ , podanych w czwartej kolumnie tablicy na str. 10 Rocznika

$$\theta = \theta_0 + n\Delta_0^I, \quad \text{gdzie } n = \frac{6^h 35^m 39.8300^s}{24^h} = +0.274\,766\,551$$

|  | $\theta$  | $\Delta_0^I$  |
|--|---|---|
| 2021 sierpień 12 <sup>d</sup> 0 <sup>h</sup> UT1 | 21 <sup>h</sup> 21 <sup>m</sup> 33 <sup>s</sup> .8915 | 24 <sup>h</sup> 03 <sup>m</sup> 56 <sup>s</sup> .5469 |
|  | 24 <sup>h</sup> +21 25 30.4384                        |   |
| $\theta_0$                                       | =   | 21 <sup>h</sup> 21 <sup>m</sup> 33 <sup>s</sup> .8915 |
| $n\Delta_0^I$                                    | =   | + 6 36 44.8252  |
| $\theta$   | =   | 3 58 18.7167  |

### Słońce (str. 12÷19)

Początkiem okresu juliańskiego, od którego liczy się daty juliańskie ( $JD$ ), jest moment  $-4712$  styczeń 1<sup>d</sup> 12<sup>h</sup>  $TT$  czyli południe  $TT$  1 stycznia 4713 r. p.n.e.

Pozorne współrzędne równikowe ( $CIP$ ) Słońca: rektascensja ( $\alpha_{app}^{CIO}$ ) odniesiona do  $CIO$ , rektascensja ( $\alpha_{app}^\gamma$ ) odniesiona do punktu równonocy wiosennej i deklinacja ( $\delta_{app}$ ), obliczone w odstępach dobowych w skali czasu  $TT$ . Zawierają one wpływ aberracji rocznej. Zgodnie z zaleceniem IAU,  $CIO$  (poprzednio określany jako  $CEO$ ) zastąpił punkt równonocy wiosennej jako punkt początkowy liczenia rektascensji. Wynikająca stąd różnica w rektascensji Słońca wynosi średnio w roku 2021:  $\alpha_{app}^{CIO} - \alpha_{app}^\gamma \approx -66^s.9$ . Wartość deklinacji nie ulega zmianie.

W kolejnych kolumnach tablic zawarto:

- $V_\delta/1^h$ , przemianę deklinacji pozornej Słońca na jedną godzinę;
- $R$ , widomy kątowy promień tarczy słonecznej, obliczony przy założeniu, że liniowa średnica tarczy słonecznej  $D_\odot = 1.392 \times 10^9 \text{ m}$ ;
- $\pi$ , horyzontalną paralaksę równikową Słońca;
- $E$ , równanie czasu — jest to różnica pomiędzy rektascensją Słońca średniego i rektascensją środka tarczy Słońca prawdziwego. Jest to także różnica pomiędzy kątem godzinnym środka Słońca prawdziwego i kątem godzinnym Słońca średniego. Uwaga: w tablicach podano równanie czasu  $E$  zwiększone o 12<sup>h</sup>;
- $V_E/1^h$ , przemianę równania czasu na jedną godzinę.

Wschody i zachody Słońca odnoszą się do momentów wschodu i zachodu górnego brzegu tarczy słonecznej w Warszawie (Obserwatorium Politechniki) w czasie środkowoeuropejskim ( $UTC + 1^h$ ). W obliczeniach uwzględniono refrakcję średnią i paralaksę Słońca. Chcąc wyrazić wschody i zachody w czasie wschodnioeuropejskim, który w Polsce jest czasem letnim, należy do momentów podanych w Roczniku dodać jedną godzinę.

*Przykład obliczenia pozornych współrzędnych równikowych Słońca*

- 4) Obliczyć pozorne współrzędne równikowe Słońca w Niebieskim Pośrednim Systemie Odniesienia  $IRS_{\text{NIEBIESKI}}$  na moment 2021 sierpień  $12^d 17^h 45^m 35^s$  czasu wschodnioeuropejskiego za pomocą wzoru interpolacyjnego Stirlinga

$$u = u_0 + n\Delta_0^I + \frac{n^2}{2}\Delta_0^{II} + \dots$$

Ze str. 16 Rocznika wypisujemy, podane na  $0^h$  czasu  $TT$ , wartości  $\alpha_{app}^{CIO}$  oraz  $\delta_{app}$  na okalające daty i tworzymy różnice

|   | $\alpha_{app}^{CIO}$ |            | $\delta_{app}$         |
|---|----------------------|------------|------------------------|
| 11  | $9^h 22^m 52^s.526$  |            | $15^\circ 15' 46''.02$ |
|   | $+226^s.761$         |            | $-1075''.04$           |
| 2021.VIII.12 <sup>d</sup> 0 <sup>h</sup> $TT$ | $9\ 26\ 39.287$      | $-0^s.574$ | $14\ 57\ 50.98$        |
|   | $+226.187$           |            | $-1089.34$             |
| 13  | $9\ 30\ 25.474$      |            | $14\ 39\ 41.64$        |

Zadany moment podany jest w czasie wschodnioeuropejskim. Argumentem w tablicach Słońca jest natomiast Czas Ziemi  $TT$ , toteż w tymże czasie należy wyrazić zadany moment jeszcze przed rozpoczęciem rachunku interpolacyjnego. Przeliczenie to wykonuje się w sposób następujący:

|                                    |                      |           |
|------------------------------------|----------------------|-----------|
| czas wschodnioeuropejski           | $17^h 45^m 35^s.000$ |           |
| minus redukcja strefowa $\Delta Z$ | $- 2\ 00\ 00.000$    |           |
| $UTC$                              | $15\ 45\ 35.000$     |           |
| plus ( $TAI - UTC$ )               | $+ 37.000$           | wzór (60) |
| $TAI$                              | $15\ 46\ 12.000$     |           |
| plus ( $TT - TAI$ )                | $+ 32.184$           | wzór (44) |
| $TT$                               | $15\ 46\ 44.184$     |           |

Teraz można obliczyć współczynnik interpolacyjny

$$n = \frac{15^h 46^m 44^s.184}{24^h} = +0.657\ 456$$

skąd

$$\frac{n^2}{2} = +0.2161$$

Obliczenie współrzędnych przebiega następująco:

|                              | $\alpha_{app}^{CIO}$  | $\delta_{app}$          |
|------------------------------|-----------------------|-------------------------|
| $u_0$                        | $= 9^h 26^m 39^s.287$ | $+14^\circ 57' 50''.98$ |
| $n\Delta_0^I$                | $= + 2\ 28.8967$      | $- 11\ 51.492$          |
| $\frac{n^2}{2}\Delta_0^{II}$ | $= - 0.1241$          | $- 3.091$               |
| $u$                          | $= 9^h 29^m 08^s.060$ | $+14^\circ 45' 56''.40$ |

Deklinację pozorną można także obliczyć posługując się przemianami zamieszczonymi w następnej za deklinacją kolumnie, na mocy wzoru

$$u = u_0 + np \left[ V_0 + \frac{n}{2}\Delta_0^I(V_0) + \dots \right]$$

Tym razem, poszukując deklinacji na ten sam moment co poprzednio, wypisujemy ze str. 16, oprócz wartości  $\delta_{app}$ , także jej przemiany na jedną godzinę,  $V_\delta/1^h$  na okalające daty, a następnie tworzymy różnice przemian

|   |             |            |
|---|-------------|------------|
| 11  | $-44''.492$ | $-0''.602$ |
| 2021.VIII.12 <sup>d</sup> 0 <sup>h</sup> $TT$ | $-45.094$   | $-0.588$   |
| 13  | $-45.682$   |            |

Współczynnik interpolacyjny pozostaje taki sam jak poprzednio, tj.  $n = +0.657\ 456$ .

Współczynnik  $p$ , który przedstawia stosunek interwału funkcji  $u$ , do interwału jej przemiany  $V$ , równa się

$$p = \frac{24^h}{1^h} = 24$$

Dalszy rachunek przebiega następująco:

|               |              |                              |               |            |                           |
|---------------|--------------|------------------------------|---------------|------------|---------------------------|
| $\frac{n}{2}$ | $= +0.3287$  | $V_0$                        | $= -45''.094$ | $\delta_0$ | $= +14^\circ 57' 50''.98$ |
| $np$          | $= +15.7789$ | $\frac{n}{2}\Delta_0^I(V_0)$ | $= - 0.196$   | $npV$      | $= - 11\ 54.622$          |
|               |              | $V$                          | $= -45''.290$ | $\delta$   | $= +14^\circ 45' 56''.36$ |

- 5) Znaleźć kąt godzinny Słońca prawdziwego względem południka Borowej Góry na moment 2021 maj 18<sup>d</sup> 14<sup>h</sup> 22<sup>m</sup> 10<sup>s</sup> czasu wschodnioeuropejskiego.

Kąt godzinny Słońca prawdziwego oblicza się ze wzoru  $t = T + E - \mu\Delta T'$ , gdzie  $T$  jest czasem średnim słonecznym odniesionym do południka lokalnego,  $E$  efemerydalnym równaniem czasu, a  $\mu\Delta T'$  poprawką związaną z przejściem pomiędzy czasem  $TT$ , w którym jest wyrażone równanie czasu, a czasem  $UT1$ . Wielkość  $\mu = 0.002\,737\,909\,350\,795$  (por. wzór ze str. 165), zaś  $\Delta T'$  jest zdefiniowana za pomocą wzoru

$$\Delta T' = TT - UT1$$

Przy przeliczaniu kąta godzinnego Słońca prawdziwego w 2021 roku z dokładnością 0<sup>s</sup>.001 wystarczy przyjąć  $\Delta T' = 69^s$ , skąd  $\mu\Delta T' = 0^s.189$ .

|   |  |                            |
|---|--|----------------------------|
| Czas wschodnioeuropejski                                | 14 <sup>h</sup> 22 <sup>m</sup> 10 <sup>s</sup> .000 |                            |
| minus redukcja strefowa $\Delta Z$                      | – 2 00 00.000  |                            |

| TT                                 | 12 23 19.184   |           |

Ze str. 15 Rocznika wypisujemy na najbliższą północ  $TT$  zwiększone o 12 godzin równanie czasu oraz przemiany równania czasu na okalające daty, a następnie obliczamy pierwsze różnice przemian

|  |              |         |
|--|--------------|---------|
| 17   | –0.0748      | –0.0224 |
| 2021.V.18 <sup>d</sup> 0 <sup>h</sup> $TT$ | 12 03 34.307 | –0.0972 |
| 19   | –0.1194      | –0.0222 |

liczymy współczynniki

$$n = \frac{12\,23\,19.184}{24^h} = +0.516\,194, \quad \frac{n}{2} = +0.2581, \quad p = \frac{24^h}{1^h} = 24, \quad np = +12.3887$$

i obliczamy interpolowaną wartość równania czasu

$$E + 12^h = 12\,03\,34.307 - 12.3887 (0.0972 + 0.2581 \times 0.0223) = 12\,03\,33.032$$

- 6) Wyrazić w czasie uniwersalnym średnim  $UT1$  moment, w którym w dniu 18 maja 2021 roku kąt godzinny Słońca prawdziwego względem południka Borowej Góry wynosi 1<sup>h</sup>49<sup>m</sup>51<sup>s</sup>.424.

|  |   |                         |
|--|---|-------------------------|
| Kąt godz. Słońca prawdz. wzgl. południka BG                  | 1 <sup>h</sup> 49 <sup>m</sup> 51 <sup>s</sup> .547 |                         |
| minus długość geogr. Borowej Góry                            | – 1 24 08.914                                       | ze str. 7               |
| kąt godz. Słońca prawdz. wzgl. poł. Greenwich                | 0 25 42.633   |                         |
| minus $(E + 12^h)$   | –12 03 33.032 <sup>a)</sup>                         |                         |
| kąt godz. Sł. śr. wzgl. poł. Greenwich minus 12 <sup>h</sup> | 12 22 09.601  |                         |
| plus $\mu\Delta T'$  | + 0.189   | zob. przykład poprzedni |
| UT1  | 12 22 09.790  |                         |

- a) Do obliczenia równania czasu potrzeba znać a priori czas  $TT$  w zadanym momencie, ale niedokładność paru sekund nie ma znaczenia. Przybliżoną w tych granicach wartość czasu  $TT$  obliczamy w sposób następujący:

|  |  |                            |
|--|--|----------------------------|
| kąt godz. Słońca prawdz. wzgl. poł. Greenwich<br>minus $(E + 12^h)$        | $0^h 25^m 42.63^s$<br>$-12\ 03\ 33.07$ <sup>b)</sup> |                            |
| kąt godz. Sł. śr. wzgl. poł. Greenwich minus $12^h$<br>plus $\mu\Delta T'$ | $12\ 22\ 09.56$<br>$+ \quad \quad 0.19$              | zob. przykład poprzedni    |
| $UT1$<br>minus $[UT1 - UTC]_{\text{IERS}}$                                 | $12\ 22\ 09.75$<br>$+ \quad \quad 0.21$              | ze str. 41 (interpolowane) |
| $UTC$<br>plus $(TAI - UTC)$  | $12\ 22\ 09.96$<br>$+ \quad \quad 37.00$             | wzór (60)                  |
| $TAI$<br>plus $(TT - TAI)$   | $12\ 22\ 46.96$<br>$+ \quad \quad 32.18$             | wzór (44)                  |
| $TT$   | $12\ 23\ 19.14$                                      |                            |

- b) Do obliczenia przybliżonej wartości równania czasu współczynnik interpolacyjny  $np$  określamy na podstawie wartości kąta godzinowego Słońca względem południka Greenwich zmniejszonej o  $12^h$ , czyli przybliżonej (błędnej głównie o wartość równania czasu minus  $\Delta T'$ ) wartości czasu  $TT$ . Możemy tak zrobić, ponieważ przemiany równania czasu są podane na  $0^h TT$ , a zatem  $n = TT/24^h$ , przy czym są to przemiany godzinowe, zatem  $p = 24^h/1^h$ . Tak więc

$$np \simeq \frac{\text{czas sł. pr. Greenwich}}{1^h} = \frac{0^h 26^m - 12^h}{1^h} = 12.4$$

Przybliżoną wartość równania czasu (zwiększoną o  $12^h$ ) interpolujemy liniowo, korzystając z danych ze str. 15, podobnie jak w przykładzie poprzednim

$$E + 12^h = 12\ 03\ 34.31 - 12.4 \times 0.10 = 12\ 03\ 33.07$$

Z tą prowizoryczną wartością równania czasu kończymy rachunek przybliżonej wartości czasu  $TT$ . Następnie liczymy dokładnie współczynniki interpolacyjne

$$n = \frac{12\ 23\ 19.14}{24^h} = +0.516\ 194, \quad \frac{n}{2} = +0.2581, \quad np = 12.3886$$

a wreszcie ostateczną wartość równania czasu, z którą kończymy obliczenia zasadnicze. Tu również korzystamy z danych ze str. 15, użytych w przykładzie poprzednim

$$E + 12^h = 12\ 03\ 34.307 - 12.3886 (0.0972 + 0.2581 \times 0.0223) = 12\ 03\ 33.032$$

Pozorne współrzędne równikowe Słońca w układzie równikowym związanym z punktem równonocy wiosennej oblicza się według tego samego schematu z wykorzystaniem wielkości  $\alpha_{app}^\gamma$  w miejsce  $\alpha_{app}^{CIO}$ .

### Księżyc (str. 20÷27)

Pozorne współrzędne równikowe (CIP) Księżyca: rektascensja ( $\alpha_{app}^{CIO}$ ) odniesiona do CIO, rektascensja ( $\alpha_{app}^\gamma$ ) odniesiona do punktu równonocy wiosennej i deklinacja ( $\delta_{app}$ ), obliczone w odstępach dobowych w skali czasu  $TT$ .

W kolejnych kolumnach tablic zawarto:

- $V_\delta/1^h$ , przemianę deklinacji pozornej Księżyca na jedną godzinę;
- $R$ , pozorny promień tarczy Księżyca;
- $\pi$ , horyzontalną paralaksę równikową Księżyca;
- Wiek Księżyca, interwał czasu liczony w dobach od nowiu.

Wschody i zachody Księżyca odnoszą się do momentów wschodu i zachodu górnego brzegu tarczy Księżyca w Warszawie (Obserwatorium Politechniki) w czasie środkowoeuropejskim ( $UTC + 1^h$ ). W obliczeniach uwzględniono refrakcję średnią i paralaksę Księżyca na dany moment. Chcąc wyrazić wschody, górowania i zachody w czasie wschodnioeuropejskim, który w Polsce jest czasem letnim, należy momenty podane w Roczniku zwiększyć o jedną godzinę. Godzina 24 otrzymana z dodawania byłaby wtedy godziną 0 dnia następnego.

### Pozorne położenie Słońca (str. 28)

Momenty wstępowania Słońca w poszczególne znaki Zodiaku podano w czasie  $TT$ , który w tym wypadku można utożsamiać z czasem uniwersalnym.

## Planety (str. 28÷29)

Pozorne współrzędne równikowe: rektascensja ( $\alpha_{app}^{CIO}$ ) i deklinacja ( $\delta_{app}$ ) planet: Merkurego, Wenus, Marsa obliczone w odstępach 10 dniowych zaś Jowisza, Saturna, Urana i Neptuna w odstępach 20 dniowych, w skali czasu  $TT$ . Są one odniesione do równika  $CIP$  oraz do  $CIO$ .

W kolejnych kolumnach tablic zawarto:

- $\pi$ , horyzontalną paralaksę równikową planety;
- $R$ , pozorny promień tarczy planety.

## Fazy Księżyca, perigeum, apogeum (str. 29)

Momenty osiągnięcia faz są podane do 1 minuty, momenty przejścia Księżyca przez perigeum i apogeum do 1 godziny.

Lunacja to cykl faz Księżyca pomiędzy dwoma kolejnymi nowiami. Czas trwania lunacji nosi nazwę miesiąca synodycznego i zwykle oba te pojęcia są utożsamiane. Zgodnie z propozycją Browna lunacje są numerowane kolejno od 17 stycznia 1923 roku (w nawiasach podano numery kolejnych lunacji).

Paralaksa Księżyca w perigeum i apogeum przyjmuje wartości ekstremalne.

## Tablice do obliczania czasu wschodu i zachodu Słońca i Księżyca poza Warszawą (str. 30÷31)

Momenty wschodu i zachodu Słońca oraz Księżyca w Warszawie, wyrażone w czasie środkowoeuropejskim, podano w tablicach na str. 12÷27. Czas wschodu i zachodu Słońca w innych miejscowościach Polski można obliczyć korzystając z danych zawartych w tablicy ze str. 30, a czas wschodu i zachodu Księżyca korzystając z danych z tablicy ze str. 31. Tablice te zawierają poprawki, jakie należy dodać (algebraicznie) do czasu wschodu i zachodu tych ciał niebieskich w Warszawie (z uwzględnieniem uwag zamieszczonych u dołu str. 30 i 31), aby otrzymać momenty wschodu i zachodu w CSE w innych miejscowościach.

*Przykład obliczenia momentów wschodów i zachodów poza Warszawą*

- 7) Obliczyć w czasie środkowoeuropejskim momenty wschodu i zachodu Słońca oraz Księżyca w dniu 9 czerwca 2021 roku w Szczecinie.

Ze str. 15 Rocznika dla Słońca i str. 23 dla Księżyca dostajemy

|      | Słońce    |            | Księżyc   |            |            |
|------|-----------|------------|-----------|------------|------------|
|      | wschód    | zachód     | wschód    | górow.     | zachód     |
| VI.9 | $3^h16^m$ | $19^h55^m$ | $2^h39^m$ | $10^h47^m$ | $19^h09^m$ |

Obliczamy dla Księżyca odstęp czasu  $\tau$ , przy czym  $\tau_E$  jest to odstęp czasu między wschodem a następującym po nim górowaniem, zaś  $\tau_W$  przedstawia odstęp czasu między poprzedzającym dany zachód górowaniem a momentem zachodu

$$\tau_E = 10^h47^m - 2^h39^m = 8^h08^m, \quad \tau_W = 19^h09^m - 10^h47^m = 8^h22^m$$

Do obliczeń przyjmujemy współrzędne geograficzne Szczecina

$$\varphi = +53^\circ26' \quad \lambda = 14^\circ33' = +0^h58^m2$$

Najpierw interpolujemy dla szerokości geograficznej Szczecina dane ze str. 30 i 31, i układamy dla nich tabelki poprawek. Dla Słońca interpolujemy w wierszach okalających dat, a dla wschodu Księżyca w wierszach najbliższych  $\tau$  (dla zachodu Księżyca przyjmujemy tę samą wyinterpolowaną wartość z przeciwnym znakiem). Obliczamy także różnicę długości geograficznych Szczecin—Warszawa. Długość geograficzną Warszawy przyjmujemy przy tym równą  $+1^h24^m0$ , tj. równą długości Obserwatorium Politechniki Warszawskiej (str. 7), do którego odnoszą się momenty wschodów i zachodów Słońca i Księżyca w Warszawie.

|       | Słońce  |         | $\tau$    | Księżyc |         | długość geogr.   |            |
|-------|---------|---------|-----------|---------|---------|------------------|------------|
|       | wsch.   | zach.   |           | wsch.   | zach.   | Szczecin         | $0^h58^m2$ |
| V.31  | $-6^m7$ | $+6^m7$ | $8^h10^m$ | $-5^m6$ |         | W-wa Obs. PW     | 1 24.0     |
| VI.10 | $-7^m2$ | $+7^m3$ | $8^h20^m$ | $-6^m2$ | $+6^m2$ | $-\Delta\lambda$ | $+25.8$    |
|       |         |         | $8^h30^m$ |         | $+6^m9$ |                  |            |

Poprawki na zadaną datę i dla odstępów czasu  $\tau$  interpolujemy liniowo. Wyinterpolowane poprawki dodajemy algebraicznie wraz z różnicą długości (długość Warszawy minus długość Szczecina) do danych dla Warszawy. Wyniki otrzymujemy w czasie środkowoeuropejskim.

|      |                       | Słońce    |            | Księżyc   |            |
|------|-----------------------|-----------|------------|-----------|------------|
|      |                       | wschód    | zachód     | wschód    | zachód     |
| VI.9 | Warszawa cz. śr. eur. | $3^h16^m$ | $19^h55^m$ | $2^h39^m$ | $19^h09^m$ |
|      | poprawka w szerokości | -7.2      | +7.2       | -5.5      | +6.3       |
|      | poprawka w długości   | +25.8     | +25.8      | +25.8     | +25.8      |
| VI.9 | Szczecin cz. śr. eur. | $3^h35^m$ | $20^h28^m$ | $2^h59^m$ | $19^h41^m$ |

### Poprawki do obliczeń momentów początku brzasku i końca zmierzchu cywilnego w Warszawie (str. 31)

Podano poprawki dla Warszawy 3 razy w miesiącu. Na inne dni wystarczy interpolować liniowo. Błąd wyniku końcowego nie przekracza 2 minut.

Odległość zenitalną środka Słońca w momentach początku brzasku i końca zmierzchu cywilnego przyjęto równą  $96^\circ30'$ .

### Wschód i zachód Słońca w niektórych miastach Polski (str. 32÷33)

Podano w czasie środkowoeuropejskim momenty wschodu i zachodu górnego brzegu tarczy słonecznej we wszystkie niedziele dla następujących miast polskich: Białegostoku, Bydgoszczy, Gdańska, Katowic, Kielc, Koszalina, Krakowa, Lublina, Łodzi, Olsztyna, Opola, Poznania, Rzeszowa, Szczecina, Wrocławia i Zielonej Góry.

### Wschód i zachód Słońca w niektórych stolicach europejskich (str. 34)

Podano w czasie środkowoeuropejskim momenty wschodu i zachodu górnego brzegu tarczy słonecznej dwa razy w miesiącu dla następujących stolic europejskich: Aten, Belgradu, Berlina, Budapesztu, Bukaresztu, Helsinek, Lizbony, Londynu, Madrytu, Moskwy, Paryża, Pragi, Rzymu, Sofii, Sztokholmu i Wiednia.

### Kalendarz Astronomiczny (str. 35)

Kalendarz Astronomiczny umożliwia odczytanie momentów wschodu i zachodu w Warszawie w czasie środkowoeuropejskim: Słońca, Merkurego, Wenus, Marsa, Jowisza i Saturna, a także początku brzasku cywilnego i astronomicznego oraz końca zmierzchu cywilnego i astronomicznego.

### Konfiguracje planet (str. 37)

Tablica konfiguracji planet zawiera momenty koniunkcji planet Układu Słonecznego ze Słońcem, Księżycem oraz koniunkcji wzajemnych, a także momenty elongacji planet wewnętrznych i opozycji planet zewnętrznych.

Koniunkcja oznacza moment, w którym odległość kątowa na sferze niebieskiej danych dwóch ciał jest minimalna.

Elongacja i opozycja oznaczają z kolei największą, względną, kątową odległość planety i Słońca na sferze niebieskiej.

Dwie ostatnie kolumny tablicy przedstawiają, odpowiednio, odległość kątową i położenie danej planety w stosunku do drugiego, wymienionego ciała Układu Słonecznego w momencie koniunkcji gdzie: N — oznacza, że wartość deklinacji planety jest większa niż wartość deklinacji drugiego ciała, S — przeciwnie.

### Zaćmienia Słońca i Księżyca (str. 38÷39)

Podano ogólne informacje o zaćmieniach Słońca i Księżyca. Dane liczbowe dotyczące zaćmień Słońca i Księżyca zaczerpnięto ze stron internetowych NASA (F. Espenak, J. Anderson, <http://eclipse.gsfc.nasa.gov/eclipse.html>).

## Współrzędne bieguna *CIP* („chwilowego” bieguna północnego Ziemi) oraz poprawka do czasu uniwersalnego (str. 40÷41)

Współrzędne  $x_{\text{IERS}}$ ,  $y_{\text{IERS}}$  Niebieskiego Bieguna Pośredniego *CIP* („chwilowego” bieguna północnego Ziemi) na lata 2019–2020 podano w pięciodniowych interwałach wraz z datą oraz zmodyfikowaną datą juliańską (*MJD*). Są one wyrażone w układzie płaskich współrzędnych prostokątnych o początku w *IRP* (IERS Reference Pole) w systemie *ITRS*. Do roku 1987 początkiem tego układu był *CIO\** (Conventional International Origin) w systemie *BTS* (BIH Terrestrial System).

Współrzędne te (nie wyrównywane) zostały obliczone na podstawie wykonanych różnymi technikami obserwacji, których wyniki są przekazywane do IERS i sprowadzone do wspólnego układu za pomocą odpowiednich, systematycznych, właściwych dla danej techniki poprawek. Oś  $x$  tego układu jest styczna do południka zerowego *ITRS* (*IRM* — IERS Reference Meridian) ze zwrotem w kierunku Greenwich, a oś  $y$  jest skierowana na zachód. Relacje pomiędzy  $\lambda_0$ ,  $\varphi_0$  i  $A_0$ , oznaczającymi odpowiednio długość, szerokość i azymut, odniesione do *IRP* oraz  $\lambda_{\text{CIP}}$ ,  $\varphi_{\text{CIP}}$  i  $A_{\text{CIP}}$ , oznaczającymi chwilowe współrzędne i azymut odniesione do *CIP* (bardzo bliskiego chwilowemu biegunowi Ziemi), wyrażają następujące wzory:

$$\begin{aligned}\lambda_0 &= \lambda_{\text{CIP}} - \frac{1}{15} (x'' \sin \lambda_0 + y'' \cos \lambda_0) \tan \varphi_0 \\ \varphi_0 &= \varphi_{\text{CIP}} - (x'' \cos \lambda_0 - y'' \sin \lambda_0) \\ A_0 &= A_{\text{CIP}} - (x'' \sin \lambda_0 + y'' \cos \lambda_0) \sec \varphi_0\end{aligned}\tag{74}$$

We wzorach (74) długości geograficzne punktów leżących na wschód od Greenwich mają wartości dodatnie, a azymuty liczy się od północy zgodnie z ruchem wskazówek zegara. Wielkości  $x''$  i  $y''$  odpowiadają współrzędnym płaskim  $x_{\text{IERS}}$ ,  $y_{\text{IERS}}$  bieguna *CIP* wyrażonym w sekundach łuku.

Poprawkę  $\Delta\lambda = UT1 - UT0$ , która służy do przejścia od czasu uniwersalnego południka *TIO* w *IRS* do czasu uniwersalnego południka zerowego *ITRS* Greenwich, można odnaleźć w pierwszym ze wzorów (74). Mamy mianowicie

$$\Delta\lambda = UT1 - UT0 = -\frac{1}{15} (x'' \sin \lambda_0 + y'' \cos \lambda_0) \tan \varphi_0\tag{75}$$

Oprócz współrzędnych bieguna *CIP* tablica zawiera także różnice  $UT1 - UTC$ . Pozwalają one na przejście od Czasu Uniwersalnego Koordynowanego *UTC* do średniego czasu uniwersalnego  $UT1$ .

Wielkości  $\Delta T_s = UT2 - UT1$ , które przedstawiają sezonowe nieregularności ruchu obrotowego Ziemi, są przedstawiane od szeregu lat za pomocą wzoru

$$\Delta T_s = +0^s022 \sin 2\pi\tau - 0^s012 \cos 2\pi\tau - 0^s006 \sin 4\pi\tau + 0^s007 \cos 4\pi\tau\tag{76}$$

We wzorze (76)  $\tau$  oznacza część roku, jaka upłynęła od jego początku do zadanego momentu.

Współrzędne bieguna *CIP* są odniesione do układu o początku w *IRP*, przy czym do opracowania końcowych wyników  $UT1 - UTC$  są przyjmowane wyrównane współrzędne w systemie *ITRS*.

Dane dotyczące bieguna *CIP* oraz różnice  $UT1 - UTC$  na koniec roku 2019 i większą część roku 2020 zamieszczono na str. 40. Dane stanowią wynik obliczeń prowadzonych na bieżąco przez IERS, aktualizowanych dwa razy w tygodniu i publikowanych jako tzw. rozwiązanie C04<sup>20)</sup> oraz w wydawanych co miesiąc przez IERS biuletynach B<sup>21)</sup>. Tablica zawiera dane dostępne w chwili wydawania Rocznika.

Przybliżone, przewidywane, dostępne w chwili wydawania Rocznika, współrzędne bieguna *CIP* oraz różnice  $UT1 - UTC$  na koniec roku 2020 i znaczną część roku 2021 zostały przedstawione w tablicy na str. 41. Dane te zaczerpnięto z biuletynu A<sup>22)</sup>, wydawanego przez IERS Rapid Service/Prediction Center w US Naval Observatory i podano z dokładnością do dwóch cyfr znaczących.

<sup>20)</sup> Dane te są dostępne pod adresem internetowym: <ftp://ftp.iers.org/products/eop/long-term/>.

<sup>21)</sup> Biuletyny B są dostępne pod adresem internetowym: <ftp://hpiers.obspm.fr/eop-pc/bul/bulc/>.

<sup>22)</sup> Biuletyny A są dostępne pod adresem internetowym: <ftp://maia.usno.navy.mil/ser7/ser7.dat> lub <ftp://cddis.gsfc.nasa.gov/pub/p>

## Miejsca średnie gwiazd (str. 42÷60)

Miejsca średnie ( $\alpha_{2021.5}$ ,  $\delta_{2021.5}$ ) gwiazd wybranych z katalogu FK5 (*Fifth Fundamental Catalogue*), ich przemiany roczne  $VA_\alpha$ ,  $VA_\delta$  oraz roczne ruchy własne  $\mu_\alpha$ ,  $\mu_\delta$ , obliczono zgodnie z uchwałą IAU (Grenoble, 1976) (patrz str. 160 niniejszego RA), to znaczy w systemie stałych IAU1976, wychodząc z pozycji katalogowych FK5, odniesionych do epoki J2000.0 i ekwinokcjum FK5. Miejsca średnie gwiazd są podane na epokę 2021.5. Wybór zawiera 475 gwiazd północnej półkuli niebieskiej, w tym 460 gwiazd o deklinacji nie większej niż  $81^\circ$  i 15 gwiazd bliskobiegunowych, których deklinacje przekraczają  $81^\circ$  oraz 474 gwiazdy południowej półkuli niebieskiej, z których 5 leży blisko bieguna południowego.

Jasności gwiazd o deklinacjach zawartych w granicach od  $-81^\circ$  do  $+81^\circ$  nie przekraczają  $5.68^m$ . Oznaczenia *pr*, *sq*, *cg*, umieszczone przy numerach gwiazd (wg FK5), odnoszą się do gwiazd podwójnych i oznaczają odpowiednio: *praecedens* — poprzedzająca, *sequens* — następująca, *centrum gravitatis* — środek mas. Znak \* przy numerze gwiazdy (wg FK5) oznacza, że w Roczniku są podane również jej pozycje pozorne. W kolumnie jasności gwiazdowych (magnitudo) literą *v* oznaczono gwiazdy zmienne — jasności gwiazd pochodzą z katalogu FK4. Tablice zawierają ponadto typy widmowe (Sp) gwiazd oraz ich paralaksy ( $\pi$ ) zaczerpnięte z katalogu FK5.

## Barycentryczne pozycje gwiazd w systemie ICRS (BCRS) (str. 61÷79)

Tablice barycentrycznych pozycji gwiazd, zgodnie z Rezolucją B2 XXIII Zgromadzenia Generalnego IAU (Kyoto, 1997), zostały opracowane na podstawie katalogu Hipparcos uznanego za podstawową realizację ICRS w zakresie widma optycznego. Tablice zawierają te same gwiazdy, których miejsca średnie na epokę J2021.5 zamieszczono w tablicach na str. 42÷60. Zamieszczone w niniejszym Roczniku Astronomicznym barycentryczne pozycje ICRF gwiazd na epokę J2000.0 obliczono korzystając z ich pozycji podanych w katalogu Hipparcos (odniesionego do epoki J1991.25), w oparciu o tzw. „standardowy model ruchu gwiazd” (zakładający ich prostoliniowy ruch w trójwymiarowej przestrzeni), z uwzględnieniem ruchów własnych w rektascensji i deklinacji (Hipparcos) oraz prędkości radialnych. Katalog Hipparcos nie zawiera danych o prędkościach radialnych gwiazd. Prędkości radialne  $V_R$  większości gwiazd pochodzą więc z katalogu FK6, a w wypadku gwiazd, których on nie obejmuje, z katalogu FK5.

W tablicach barycentrycznych pozycji gwiazd dla każdej gwiazdy podano jej numer katalogowy według katalogu Hipparcos (HIP) oraz według katalogu FK5, jasność gwiazdy (magnitudo), jej pozycję barycentryczną  $\alpha_{ICRF}$  i  $\delta_{ICRF}$  oraz ruchy własne  $\mu_\alpha$  i  $\mu_\delta$ , przeliczone na epokę J2000.0, a także paralaksę roczną  $\pi$  oraz typ widmowy (Sp). Wszystkie powyższe dane zaczerpnięte zostały z katalogu Hipparcos.

Oznaczenia *pr*, *sq*, *cg* umieszczone przy numerach gwiazd (HIP) odnoszą się do gwiazd podwójnych i oznaczają, podobnie jak w tablicach miejsc średnich, odpowiednio: *praecedens* — poprzedzająca, *sequens* — następująca, *centrum gravitatis* — środek mas. Znak \* przy numerze gwiazdy (HIP) oznacza, że w Roczniku są podane również jej pozycje pozorne. W kolumnie jasności gwiazdowych (magnitudo) literą *v* oznaczono gwiazdy zmienne.

W przypadku gwiazd podwójnych o wyróżniającej się jasności, np. Syriusz lub Biegunowa, ich pozycje barycentryczne odnoszą się do środka mas układu podwójnego.

## Wielkości redukcyjne (str. 80÷ 87)<sup>23)</sup>

Wielkości redukcyjne podano w odstępach dobowych na  $0^h$  Dynamicznego Czasu Gwiazdowego *SDT*. Służą one do obliczania miejsc pozornych  $\alpha_{app}^\gamma$ ,  $\delta_{app}$ .

Współrzędne pozorne gwiazdy oblicza się następująco:

$$\begin{aligned}\alpha_{app}^\gamma &= \alpha_0 + (A + A')a + (B + B')b + Cc + Dd + E + \mu_\alpha \tau + I_\alpha \tan^2 \delta_0 \\ \delta_{app} &= \delta_0 + (A + A')a' + (B + B')b' + Cc' + Dd' + \mu_\delta \tau + I_\delta \tan \delta_0\end{aligned}\quad (77)$$

gdzie  $\alpha_0$ ,  $\delta_0$  to miejsca średnie na środek roku, a wielkości redukcyjne  $A$ ,  $A'$ ,  $B$ ,  $B'$  odnoszą się do precesji i nutacji

$$\begin{aligned}A + A' &= n\tau + (\Delta\Psi + d\Psi) \sin \varepsilon & A' &= d\Psi \sin \varepsilon \\ B + B' &= -(\Delta\varepsilon + d\varepsilon) & B' &= -d\varepsilon\end{aligned}\quad (78)$$

<sup>23)</sup> W świetle uchwały IAU (Montreal, 1979), metoda tu opisywana nie może być stosowana w obliczeniach wymagających wysokiej precyzji (patrz str. 160 niniejszego RA).

$C$  i  $D$  są to wielkości redukcyjne uwzględniające aberrację roczną

$$\begin{aligned} C &= 1191''.286\,16\,\dot{Y} \\ D &= -1191''.286\,16\,\dot{X} \end{aligned} \quad (79)$$

przy czym  $\dot{X}, \dot{Y}$  to składowe barycentrycznego wektora prędkości Ziemi w jednostkach astronomicznych na dobę, a  $n$  oznacza precesję roczną w deklinacji (str. 7) wyrażoną w sekundach łuku. Ułamek  $\tau$  przedstawia część roku zwrotnikowego od środka roku do danego momentu. W pierwszej połowie roku jest on ujemny, a w drugiej dodatni.

Współczynniki  $a, b, c, d$  i  $a', b', c', d'$  są obliczane ze wzorów

$$\begin{aligned} a &= \frac{1}{15} \left( \frac{m}{n} + \tan \delta \sin \alpha \right) & a' &= \cos \alpha \\ b &= \frac{1}{15} \tan \delta \cos \alpha & b' &= -\sin \alpha \\ c &= \frac{1}{15} \sec \delta \cos \alpha & c' &= \tan \varepsilon \cos \delta - \sin \delta \sin \alpha \\ d &= \frac{1}{15} \sec \delta \sin \alpha & d' &= \sin \delta \cos \alpha \end{aligned} \quad (80)$$

gdzie  $m$  oznacza precesję roczną w rektascensji (str. 7) wyrażoną w sekundach łuku.

Ruch własny gwiazdy  $\mu_\alpha$  w rektascensji i  $\mu_\delta$  w deklinacji jest podany w tablicach miejsc średnich.

Wielkość redukcyjną  $E$  oblicza się ze wzoru

$$E = \frac{p_2}{p_1} (\Delta\Psi + d\Psi) \quad (81)$$

gdzie  $p_1$  oznacza roczną precesję równika, a  $p_2$  roczną precesję ekliptyki (str. 7).

Miejsca pozorne gwiazd, których paralaksa roczna jest nie mniejsza niż  $0''.010$ , oblicza się z uwzględnieniem wpływu tej ostatniej, w myśl następujących zależności:

$$\begin{aligned} c_\pi - c &= +0.05318\pi'' d & c'_\pi - c' &= +0.05318\pi'' d' \\ d_\pi - d &= -0.04476\pi'' c & d'_\pi - d' &= -0.04476\pi'' c' \end{aligned} \quad (82)$$

Wartości paralaks zamieszczone w tablicach na str. 42÷60 wzięto z *General Catalogue of Trigonometric Stellar Parallaxes* (Yale University Observatory, New Haven, Conn., 1952).

Przy obliczaniu miejsc pozornych gwiazd znacznie oddalonych od równika uwzględnia się wyrazy drugiego rzędu  $I_\alpha \tan^2 \delta_0$  oraz  $I_\delta \tan \delta_0$ . Dla gwiazd o deklinacjach  $\delta \approx 70^\circ$  wyrazy te mogą osiągać wartość około  $0''.01$ , a dla  $\delta \approx 80^\circ$  wartość około  $0''.02$ .

Występujące tu współczynniki  $I_\alpha$  i  $I_\delta$  oblicza się ze wzorów

$$I_\alpha = \frac{1}{15} PQ \sin 1'', \quad I_\delta = -\frac{1}{2} P^2 \sin 1'' \quad (83)$$

przy czym wielkości  $P$  i  $Q$  dane są wzorami

$$P = (A \pm D) \sin \alpha + (B \pm C) \cos \alpha, \quad Q = (A \pm D) \cos \alpha - (B \pm C) \sin \alpha \quad (84)$$

(dla gwiazd o  $\delta > 0^\circ$  należy brać znaki górne).

Nutację w długości  $\Delta\Psi$ ,  $d\Psi$  i nutację w nachyleniu  $\Delta\varepsilon$ ,  $d\varepsilon$ , a następnie wielkości redukcyjne  $A, A', B, B', C, D$  i  $E$  oraz czas gwiazdowy prawdziwy obliczono w systemie IAU1976 i w odniesieniu do standardowej epoki J2000.0.

## Miejsca pozorne gwiazd<sup>24)</sup> (str. 88÷111)

W pierwszej części tablic podano w odstępach co 10 dób gwiazdowych miejsca pozorne  $\alpha_{app}^\gamma$  i  $\delta_{app}$  w momencie górowania w południku Greenwich 48 gwiazd nieba północnego i 8 gwiazd nieba południowego z katalogu FK5. Zostały one wybrane spośród gwiazd, których pozycje średnie na epokę 2021.5 zawarto w tablicach na stronach 42÷60. Przy nazwach gwiazd zamieszczono dodatkowo ich wielkości gwiazdowe i typy widmowe. U dołu kolumny każdej gwiazdy zamieszczono: miejsca średnie na środek roku, współczynniki  $\sec \delta$  i  $\tan \delta$  pomocne przy redukcji obserwacji przejść gwiazd przez południk, dzień, w którym przypada dwukrotne górowanie w południku Greenwich oraz wartości stałych redukcyjnych  $a, a', b, b'$ , służące do dodatkowego uwzględnienia krótkookresowej części nutacji, pominiętej w efemerydach tych gwiazd, według wzorów

$$\begin{aligned}\Delta\alpha_{app}^\gamma &= A'a + B'b \\ \Delta\delta_{app} &= A'a + B'b'\end{aligned}\tag{85}$$

W drugiej części, w odstępach dobowych zamieszczono efemerydy miejsc pozornych  $\alpha_{app}^\gamma$  i  $\delta_{app}$  Polaris i czterech innych gwiazd bliskobiegunowych: 1H Dra,  $\varepsilon$  UMi,  $\delta$  UMi, 36H Cep. Efemerydy gwiazd okołobiegunowych zawierają już krótkookresową część nutacji. U dołu stronic podano daty dwukrotnego górowania<sup>25)</sup> oraz dołowania, miejsca średnie na środek roku, a także współczynniki  $\sec \delta$  i  $\tan \delta$  w odstępach co 10'' wartości deklinacji.

### Przykłady obliczenia miejsc pozornych

- 8) Obliczyć przy użyciu wzoru interpolacyjnego Stirlinga, na podstawie tablic miejsc pozornych gwiazd, współrzędne pozorne gwiazdy  $\alpha$  Tauri (FK5 168) na moment 2021 styczeń 10<sup>d</sup>12<sup>h</sup>30<sup>m</sup>00<sup>s</sup> UT1.

Ze str. 90 Rocznika wypisujemy  $\alpha_{app}^\gamma$  i  $\delta_{app}$  na okalające daty oraz obliczamy pierwsze i drugie różnice

|                         | $\alpha_{app}^\gamma$                               |        | $\delta_{app}$ |
|-------------------------|---|--------|----------------|
| 2021.I.1 <sup>d</sup> 9 | 4 <sup>h</sup> 37 <sup>m</sup> 07 <sup>s</sup> .806 |        | +16°32'59".79  |
|                         | -0.023  |        | -0.14          |

| GMST w zadanym momencie                    | 19 51                           |

<sup>24)</sup> Porównanie wartości miejsc pozornych (odniesionych zarówno do CIO jak i punktu równonocy) opartych na danych katalogowych FK5 oraz Hipparcos (zawartych w tablicach na stronach str. 122÷145) wykazuje w wypadku niektórych gwiazd duże rozbieżności. Rozbieżności te mają swe źródło w systematycznych błędach pozycji zawartych w katalogu FK5 i osiągają niekiedy wartość nawet kilkuset mas. Wspomniane rozbieżności dotyczą w szczególności gwiazd o numerach katalogowych FK5: 257 ( $\alpha$  CMa), 335 ( $\iota$  UMi), 417 ( $\zeta$  UMi) i 893 ( $\gamma$  Cep). Pozycje pozorne tych gwiazd wyznaczone w oparciu o katalog FK5 należy traktować ze szczególną ostrożnością.

<sup>25)</sup> Niezgodność tej daty z wynikającą z momentów górowania z pierwszej kolumny jest pozorna i wynika z zaokrągleń tych ostatnich do jednego miejsca po przecinku.

Współczynnik interpolacji obliczamy jako podzieloną przez  $10^d$  (interwał z jakim tablicowane są w Roczniku miejsca pozorne) różnicę pomiędzy wyrażonym w czasie gwiazdowym momentem zadany (data oraz czas gwiazdowy) a najbliższym momentem, dla którego została podana w Roczniku pozycja pozorna gwiazdy, tj. datą oraz czasem  $UT1$  (ułamek doby) wyrażonym w skali czasu gwiazdowego. Ponieważ pozycje pozorne są podawane na moment górowania gwiazdy, moment czasu gwiazdowego efemerydy jest równy rektascensji gwiazdy.

|   |           |                                 |
|---|-----------|---------------------------------|
| Czas gwiazdowy Greenwich w zadany momencie                        | 2021.I.10 | 19 <sup>h</sup> 51 <sup>m</sup> |
| epoka efemerydy (cz. gw. Gr. w momencie górowania = rektascensja) | 2021.I.11 | 4 37                            |
|   | -0        | 8 46                            |

$$\text{współczynnik interpolacyjny } n = \frac{-0^d 8^h 46^m}{10^d} = -0.0365$$

Współczynnik do interpolowania wielkości redukcyjnych obliczamy w sposób następujący: od zadanego momentu, określonego liczbą dni miesiąca oraz ułamkiem doby, odpowiadającym czasowi uniwersalnemu średniemu  $UT1$ , odejmujemy najbliższą datę (złożoną z liczby dni miesiąca i ułamka doby, odpowiadającego czasowi uniwersalnemu średniemu  $UT1$ ), na którą są podane w Roczniku wielkości redukcyjne, a w końcu, aby prowadzić interpolację w dziedzinie czasu gwiazdowego, otrzymaną różnicę dzielimy przez współczynnik 0.997 wzór (14).

|                 |                                     |
|-----------------|-------------------------------------|
| Zadany moment   | $10^d 12^h 30^m UT1 = 10^d 521 UT1$ |
| epoka efemerydy | $\frac{10.693 UT1}{-0.172}$         |
| różnica         | cz. śr. sł.                         |

$$\text{współczynnik interpolacyjny } n = \frac{-0.172}{0.997} = -0.173$$

A oto rachunek interpolacyjny za pomocą wzoru Stirlinga

$$\begin{aligned}\alpha_{app}^{\gamma} &= 4^h 37^m 07.783 - 0.0365 (-0.5 \times 0.089 + 0.5 \times 0.0365 \times 0.043) = 4^h 37^m 07.785 \\ \delta_{app} &= +16^\circ 32' 59.65 - 0.0365 (-0.5 \times 0.28 - 0.5 \times 0.0365 \times 0.00) = +16^\circ 32' 59.66 \\ A' &= -0.048 - 0.173 (0.5 \times 0.091 - 0.5 \times 1.173 \times 0.013) = -0.056 \\ B' &= +0.088 - 0.173 (0.5 \times 0.060 + 0.5 \times 0.173 \times 0.022) = +0.082\end{aligned}$$

W ostatniej części rachunku uwzględniamy w myśl wzorów (85) wpływ krótkookresowej części nutacji, którego nie obejmują współrzędne pozorne publikowane w Roczniku

|                                      |                   |                             |                       |
|--------------------------------------|-------------------|-----------------------------|-----------------------|
| $\alpha_{app}^{\gamma}$ bez kr. nut. | $4^h 37^m 07.785$ | $\delta_{app}$ bez kr. nut. | $+16^\circ 32' 59.66$ |
| $A'a$                                | - 0.0096          | $A'a'$                      | - 0.020               |
| $B'b$                                | + 0.0006          | $B'b'$                      | - 0.077               |
| $\alpha_{app}^{\gamma}$              | $4^h 37^m 07.776$ | $\delta_{app}$              | $+16^\circ 32' 59.56$ |

- 9) Obliczyć współrzędne równikowe pozorne  $\alpha_{app}^{\gamma}$  i  $\delta_{app}$  gwiazdy  $\alpha$  Tauri (FK5 168) na moment 2021 styczeń  $10^d 12^h 30^m 00^s UT1$ , wychodząc z miejsc średnich na środek roku.

Najpierw, ze str. 45 Rocznika (gwiazda nr FK5 168), wypisujemy współrzędne równikowe średnie i ruchy własne na epokę 2021.5 oraz paralaksę

$$\begin{aligned}\alpha_{2021.5} &= 4^h 37^m 09.414 & \delta_{2021.5} &= +16^\circ 33' 02.79 \\ \mu_{\alpha} &= +0.0044 & \mu_{\delta} &= -0.190 \\ \pi &= 0.048\end{aligned}$$

Dalej ze str. 80 wypisujemy wielkości redukcyjne oraz obliczamy pierwsze i drugie różnice. Na zadany moment interpolujemy za pomocą wzoru Stirlinga

| $UT1$    | $\tau$  | $A + A'$ | $B + B'$   | $C$        | $D$        | $E$        |
|----------|---------|----------|------------|------------|------------|------------|
| I. 9.696 | -0.4755 | -15.939  | -1.439     | -6.401     | +19.651    | -0.0022    |
|          |         | +111     | +19        | -315       | -125       |            |
| 10.693   | -0.4728 | -15.828  | +12 -1.420 | -23 -6.716 | +2 +19.526 | -6 -0.0021 |
|          |         | +123     | -4         | -313       | -131       |            |
| 11.691   | -0.4700 | -15.705  | -1.424     | -7.029     | +19.395    | -0.0021    |

Wielkości redukcyjne są podane w Roczniku dla każdej doby na  $0^h$  Dynamicznego Czasu Gwiazdowego ale w pierwszej kolumnie tablic podano także  $UT1$  odpowiadający momentowi  $0^h$  Dynamicznego Czasu Gwiazdowego. Dzięki temu można obliczyć współczynnik interpolacyjny na moment wyrażony w czasie uniwersalnym bez potrzeby przeliczania go na czas gwiazdowy Greenwich. Wystarczy  $UT1$  momentu zadanego zamienić na ułamek doby i odjąć od niego  $UT1$  z pierwszej kolumny, najbliższy zadanemu momentowi, a różnicę podzielić przez interwał argumentu

$$\begin{array}{rcl} \text{moment zadany} & 2021.I.10.^d521 & UT1 \\ \text{epoka efemerydy} & 2021.I.10.693 & UT1 \\ \hline \text{różnica} & -0.172 & \text{cz. śr. sł.} \\ \\ \text{współczynnik interpolacyjny} & n = \frac{-0.172}{0.997} & = -0.173 \end{array}$$

Wyniki interpolacji za pomocą wzoru Stirlinga są następujące:

$$\begin{aligned} \tau &= -0.^a4733 \\ A + A' &= -15.^s848 \\ B + B' &= -1.^s422 \\ C &= -6.^s662 \\ D &= +19.^s548 \\ E &= -0.^s0021 \end{aligned}$$

Korzystając ze wzorów (80) i (82) obliczamy stałe redukcyjne

$$\begin{array}{ll} a = +0.17198 & a' = +0.3537 \\ b = +0.00701 & b' = -0.9354 \\ c_\pi = +0.02477 & c'_\pi = +0.1493 \\ d_\pi = +0.06500 & d'_\pi = +0.1004 \end{array}$$

Końcowe obliczenia wykonujemy wg wzorów (77), przy czym wyrazy drugiego rzędu są zaniedbywalne

$$\begin{array}{rclcl} \alpha_0 & 4^h37^m09.^s414 & \delta_0 & +16^\circ33'02.^s79 \\ (A + A')a & - & 2.7255 & (A + A')a' & - & 5.605 \\ (B + B')b & - & 0.0100 & (B + B')b' & + & 1.330 \\ Cc_\pi & - & 0.1650 & Cc'_\pi & - & 0.995 \\ Dd_\pi & + & 1.2706 & Dd'_\pi & + & 1.963 \\ E & - & 0.0021 & & & \\ \mu_\alpha\tau & - & 0.0021 & \mu_\delta\tau & + & 0.090 \\ \hline \alpha_{app}^\gamma & 4^h37^m07.^s780 & \delta_{app} & +16^\circ32'59.^s57 \end{array}$$

### Barycentryczna pozycja i prędkość oraz heliocentryczna pozycja Ziemi (str. 112÷119)

W tablicach podano, obliczone w oparciu o zalecane do stosowania przez IAU efemerydy JPL DE405, barycentryczne współrzędne kartezjańskie  $X_B^E, Y_B^E, Z_B^E$  środka mas Ziemi wyrażone w jednostkach astronomicznych, składowe prędkości orbitalnej Ziemi  $\dot{X}_B^E, \dot{Y}_B^E, \dot{Z}_B^E$  wyrażone w jednostkach astronomicznych na dobę oraz heliocentryczne współrzędne kartezjańskie  $X_H^E, Y_H^E, Z_H^E$  środka mas Ziemi wyrażone w jednostkach astronomicznych. Dane podano w odstępach dobowych odniesionych do  $TCB$ .

### Współrzędne bieguna niebieskiego $CIP$ IAU2006 (str. 120÷121)

Tablice zawierają współrzędne  $X, Y$  bieguna niebieskiego  $CIP$  (IAU2006) w odniesieniu do bieguna  $GCRS$  na 2021 rok wyrażone w radianach, w odstępach dobowych, w czasie  $TT$ . Współrzędne bieguna niebieskiego  $CIP$  wraz z podaną na końcu tablic średnią wartością parametru  $s$  na 2021 rok mogą służyć do konstrukcji precesyjno-nutacyjnej macierzy obrotu, zgodnie z wzorem:

$$Q = \begin{pmatrix} Q_{11} & Q_{12} & Q_{13} \\ Q_{21} & Q_{22} & Q_{23} \\ Q_{31} & Q_{23} & Q_{33} \end{pmatrix} = \begin{pmatrix} 1 - aX^2 + saXY & s(1 - aX^2) - aXY & X \\ -s(1 - aY^2) - aXY & 1 - aY^2 - saXY & Y \\ -X + sY & -Y - sX & 1 - a(X^2 + Y^2) \end{pmatrix} \quad (86)$$

zgodnie z oznaczeniami wzoru (33).

Macierz  $Q$  jest macierzą obrotową przeprowadzającą wektor gwiazdy wyrażony w systemie  $IRS_{\text{niebieski}}$  do systemu  $GCRS$ . Chcąc dokonać przejścia odwrotnego, jak to ma miejsce np. przy obliczaniu miejsc pozornych, należy posługiwać się macierzą transponowaną  $Q^T$ .

W pierwszej części podano w odstępach co 7 dób na moment  $0^h$  UT1 miejsca pozorne  $\alpha_{app}^{CIO}$  i  $\delta_{app}$  48 gwiazd nieba północnego i 8 gwiazd nieba południowego, z zaznaczeniem przy nazwach gwiazd ich wielkości gwiazdowych i typów widmowych. Są to te same gwiazdy, dla których podano pozycje pozorne odniesione do punktu równonocy systemu FK5 na str. 88÷111. W przypadku gwiazd podwójnych (Syriusz, Biegunowa) pozycje pozorne zostały obliczone dla środków mas układów, a następnie zredukowane do środka optycznego tych układów. Dokładność wyznaczenia miejsc pozornych ( $IRS_{\text{NIEPIESKI}}$ ) dla Syriusza i Biegunowej odbiega od dokładności pozycji pozostałych gwiazd z tabeli i jest na poziomie  $0''.10$ .

Zgodnie z zaleceniami IAU proces obliczenia miejsca pozornego gwiazdy w  $IRS_{\text{NIEPIESKI}}$  ze znanej barycentrycznej pozycji gwiazdy w  $ICRF$ /Hipparcos składa się z trzech zasadniczych etapów: 1) poprawienie barycentrycznych współrzędnych gwiazdy w  $BCRF$  o ruch własny, z uwzględnieniem prędkości radialnej, 2) wykonanie transformacji Lorentza, przeprowadzającej współrzędne barycentryczne gwiazdy do współrzędnych geocentrycznych i jednocześnie  $TCB$  w  $TCG$ , 3) przejście do  $IRS_{\text{NIEPIESKI}}$  poprzez uwzględnienie precesji i nutacji, zgodnie z modelem precesyjno–nutacyjnym IAU2006. Dla uproszczenia, z zachowaniem dokładności RA, proces ten może być wykonywany w następujących etapach: 1) przeliczenie czasów, 2) przejście z  $ICRF$ /Hipparcos do  $BCRF$  poprzez uwzględnienie ruchu własnego gwiazdy (łącznie z uwzględnieniem prędkości radialnej), 3) przejście z  $BCRF$  do  $GCRF$  poprzez uwzględnienie paralaksy rocznej gwiazdy, 4) poprawienie pozycji w  $GCRF$  o wpływ grawitacyjnego ugięcia światła, 5) poprawienie pozycji w  $GCRF$  o wpływ aberracji rocznej, 6) przejście do  $IRS_{\text{NIEPIESKI}}$  poprzez uwzględnienie efektu precesyjno–nutacyjnego.

1. Czas  $TCG$  można obliczyć z czasu  $TCB$  na podstawie zależności (patrz też wzór (47))

$$TCB - TCG = L_C \times (JD - 2\,443\,144.5) \times 86\,400 + c^{-2} \mathbf{v}_e(\mathbf{x} - \mathbf{x}_e) + P$$

wykorzystując składowe barycentrycznych wektorów pozycji i prędkości Ziemi podane w tablicach RA na str. 112÷119. Pierwszy wyraz w tym wzorze jest dominujący i na połowę 2021 roku wynosi 20.8 s. Ostatni człon  $P$  odnoszący się do wyrazów okresowych nie przekracza 0.0016 s. Człon środkowy, zależny od barycentrycznego położenia i prędkości Ziemi i obserwatora, przybiera wartości poniżej 1  $\mu s$ .

Mając  $TCG$  można obliczyć  $TT$  ze wzoru (45). Na połowę roku 2021 różnica między  $TCG$  i  $TT$  wynosi 0.979 s.

2. Przejście od  $ICRF$ /Hipparcos do  $BCRF$  poprzez uwzględnienie ruchu własnego gwiazdy. Jednostkowy wektor barycentryczny  $\mathbf{p}_{ICRF}$  gwiazdy jest tworzony na podstawie barycentrycznej pozycji gwiazdy  $(\alpha_{ICRF}, \delta_{ICRF}) \equiv (\alpha, \delta)$  z katalogu Hipparcos (barycentryczne pozycje gwiazd podane w niniejszym Roczniku Astronomicznym w tablicach na str. 61÷79 odpowiadają pozycji barycentrycznej w  $ICRF$  na epokę J2000.0)

$$\mathbf{p}_{ICRF} = \begin{pmatrix} \cos \delta \cos \alpha \\ \cos \delta \sin \alpha \\ \sin \delta \end{pmatrix} \quad (87)$$

Barycentryczny wektor  $\mathbf{m}$  ruchu własnego gwiazdy ma postać

$$\mathbf{m}_{ICRF} = \begin{pmatrix} -\mu_{\alpha 0} \cos \delta \sin \alpha - \mu_{\delta 0} \sin \delta \cos \alpha + V_R \pi \cos \delta \cos \alpha \\ \mu_{\alpha 0} \cos \delta \cos \alpha - \mu_{\delta 0} \sin \delta \sin \alpha + V_R \pi \cos \delta \sin \alpha \\ \mu_{\delta 0} \cos \delta + V_R \pi \sin \delta \end{pmatrix} \quad (88)$$

gdzie  $\mu_{\alpha 0}$  i  $\mu_{\delta 0}$  oznaczają ruchy własne gwiazdy na stulecie juliańskie, prędkość radialna  $V_R$  jest wyrażona w jednostkach astronomicznych na stulecie juliańskie zaś paralaksa roczna  $\pi$  jest wyrażona w radianach.

<sup>26)</sup> Dokładność współczesnych modeli układu słonecznego oraz modelu precesyjno–nutacyjnego powoduje, że prezentacja danych o pozycjach pozornych gwiazd, w tradycyjnej formie: tabel z kilkudniowym interwałem, nie jest możliwa bez utraty dokładności pozycji pozornych — zwłaszcza wartości interpolowanych. Zapewnienie odpowiedniej dokładności danych musiałoby się wiązać z koniecznością znacznego skrócenia kroku tablicowania, a tym samym ze znacznym wzrostem objętości Rocznika. Miejsca pozorne gwiazd w Pośrednim Systemie Odniesienia, można obliczyć na dowolny zadany moment korzystając z Rocznika Astronomicznego „on-line”, dostępnego na stronach internetowych Centrum Geodezji i Geodynamiki IGiK, pod adresem: <http://www.igik.edu.pl>.

Wektor pozycji barycentrycznej  $\mathbf{p}_{BCRF}$  gwiazdy w  $BCRF$  otrzymuje się z zależności

$$\mathbf{p}_{BCRF} = \mathbf{p}_{ICRF} + t \mathbf{m}_{ICRF} \quad (89)$$

gdzie  $t = (JD(TCB) - 2\,451\,545.0)/36\,525$ .

3. Przejście od  $BCRF$  do  $GCRF$  dokonuje się poprzez uwzględnienie paralaksy rocznej

$$\mathbf{p}_{GCRF} = \mathbf{p}_{BCRF} - \pi \mathbf{E}_B \quad (90)$$

gdzie  $\mathbf{E}_B$  jest barycentrycznym wektorem pozycji Ziemi, którego współrzędne  $X_B^E, Y_B^E, Z_B^E$  z krokiem dobowym w skali czasu  $TCB$  są podane w tablicach na str. 112÷119 niniejszego RA.

4. Poprawienie pozycji gwiazdy w  $GCRF$  o wpływ grawitacyjnego zakrzywienia światła uzyskuje się dodając poprawkę  $\Delta \mathbf{p}_{graw}$  (uproszczony wzór (42))

$$\Delta \mathbf{p}_{graw} = \frac{2GM_\odot}{c^2 E_H} \frac{\mathbf{e}_H^E - (\mathbf{e}_{GCRF}^p \mathbf{e}_H^E) \mathbf{e}_{GCRF}^p}{1 + (\mathbf{e}_{GCRF}^p \mathbf{e}_H^E)} \quad (91)$$

gdzie  $\mathbf{e}_{GCRF}^p$  i  $\mathbf{e}_H^E$  są znormalizowanymi wektorami  $\mathbf{p}_{GCRF}$  i  $\mathbf{E}_H$ :  $\mathbf{e}_{GCRF}^p = \mathbf{p}_{GCRF}/|\mathbf{p}_{GCRF}|$ , a  $\mathbf{e}_H^E = \mathbf{E}_H/|\mathbf{E}_H|$ . Wektor  $\mathbf{E}_H$  jest heliocentrycznym wektorem wodzącym środka mas Ziemi, którego współrzędne  $X_H^E, Y_H^E, Z_H^E$  z krokiem dobowym w skali czasu  $TCB$  są podane w tablicach na str. 112÷119 niniejszego RA

$$\mathbf{p}'_{GCRF} = \mathbf{e}_{GCRF}^p + \Delta \mathbf{p}_{graw} \quad (92)$$

5. Poprawienie pozycji w  $GCRF$  o wpływ aberracji rocznej prowadzi do wyznaczenia właściwej pozycji  $\mathbf{p}''_{GCRF}$  gwiazdy w układzie geocentrycznym poruszającym się z prędkością  $\mathbf{V}$  w  $BCRS$ . Pozycję tę oblicza się ze wzoru

$$\mathbf{p}''_{GCRF} = \left( \beta^{-1} \mathbf{p}'_{GCRF} + \mathbf{V} + \frac{(\mathbf{p}'_{GCRF} \mathbf{V}) \mathbf{V}}{(1 + \beta^{-1})} \right) / (1 + \mathbf{p}'_{GCRF} \mathbf{V}) \quad (93)$$

gdzie  $\beta = 1/\sqrt{1 - V^2}$ , przy czym  $V = |\mathbf{V}|$ ; wektor  $\mathbf{V}$  jest liniową funkcją wektora  $\dot{\mathbf{E}}_B$  — prędkości środka mas Ziemi względem barycentrum Układu Słonecznego, którego współrzędne  $\dot{X}_B^E, \dot{Y}_B^E, \dot{Z}_B^E$  z krokiem dobowym w skali czasu  $TCB$  są podane w tablicach na str. 112÷119 niniejszego RA

$$\mathbf{V} = \dot{\mathbf{E}}_B/c = 0.005\,775\,5 \dot{\mathbf{E}}_B \quad (94)$$

$c$  jest prędkością światła wyrażoną w au/dobę.

6. Przejście od  $GCRF$  do  $IRS_{\text{NIEBESKI}}$ , w którym jest określona pozycja pozorna gwiazdy odbywa się poprzez uwzględnienie efektu precesyjno-nutacyjnego

$$\mathbf{p}_{IRS} = Q^T \mathbf{p}''_{GCRF} \quad (95)$$

gdzie  $Q$  jest macierzą precesyjno-nutacyjną (86), której elementy  $Q_{ij}$  z krokiem dobowym w skali czasu  $TCB$  są podane w tablicach na str. 120÷121 niniejszego RA<sup>27)</sup>.

Pozycję pozorną  $\alpha_{app}^{CIO}, \delta_{app}$  gwiazdy w  $IRS_{\text{NIEBESKI}}$  otrzymuje się ostatecznie ze współrzędnych kartezjańskich wektora  $\mathbf{p}_{IRS} = (x_{IRS}, y_{IRS}, z_{IRS})^T$

$$\begin{aligned} \alpha_{app}^{CIO} &= \arctan(y_{IRS}/x_{IRS}) \\ \delta_{app} &= \arcsin(z_{IRS}/\sqrt{x_{IRS}^2 + y_{IRS}^2 + z_{IRS}^2}) \end{aligned} \quad (96)$$

<sup>27)</sup> Poprawki  $\delta X$  i  $\delta Y$  współrzędnych bieguna  $CIP$  (wzory (36) i (37)) nie przekraczają  $0.2 \text{ mas}$  i nie są uwzględniane w obliczeniach miejsc pozornych w Roczniku.

- 10) Obliczyć współrzędne równikowe pozorne  $\alpha_{app}^{CIO}$  i  $\delta_{app}$  gwiazdy  $\alpha$  Tauri (HIP 21421) w systemie  $IRS_{NIEBESKI}$  na moment 2021 styczeń  $10^d 12^h 30^m 00^s$  czasu  $UT1$ , wychodząc z jej pozycji w  $ICRS$  na epokę J2000.0.

Dokonyjemy zamiany czasu  $UT1$  na  $TT$ ,  $TCG$  i  $TCB$ <sup>28)</sup>

|                            |                                    |                            |
|----------------------------|------------------------------------|----------------------------|
| $UT1$                      | $12^h 30^m 00^s 0000$              |                            |
| minus $[UT1 - UTC]_{IERS}$ | $+\frac{0.1700}{12\ 30\ 00.1700}$  | ze str. 41 (interpolowane) |
| $UTC$                      |                                    |                            |
| plus $(TAI - UTC)$         | $+\frac{37.0000}{12\ 30\ 37.1700}$ | wzór (60)                  |
| $TAI$                      |                                    |                            |
| plus $(TT - TAI)$          | $+\frac{32.1840}{12\ 31\ 09.3540}$ | wzór (44)                  |
| $TT$                       |                                    |                            |
| plus $(TCG - TT)$          | $+\frac{0.9683}{12\ 31\ 10.3223}$  | wzór (45)                  |
| $TCG$                      |                                    |                            |
| plus $(TCB - TCG)$         | $+\frac{20.5740}{12\ 31\ 30.8963}$ | wzór (47)                  |
| $TCB$                      |                                    |                            |

Z tablicy na str. 64 Rocznika wypisujemy podane na epokę J2000.0 barycentryczne współrzędne  $\alpha_{ICRF}$  i  $\delta_{ICRF}$  oraz ruchy własne  $\mu_{\alpha 0}$  i  $\mu_{\delta 0}$ , prędkość radialną  $V_R$  i paralaksę  $\pi$

$$\alpha_{ICRF} = 4^h 35^m 55.2387^s$$

$$\delta_{ICRF} = +16^\circ 30' 33.485''$$

$$\pi = 50.089\ mas = 0.000\ 000\ 243\ rad$$

$$\mu_{\alpha 0} = +4.3651\ ms/rok = +0.000\ 031\ 744\ rad/stulecie$$

$$\mu_{\delta 0} = -189.3509\ mas/rok = -0.000\ 091\ 800\ rad/stulecie$$

$$V_R = 54.1\ km/s = 1141.236\ 795\ au/stulecie \quad (1\ km/s = 21.094\ 95\ au/stulecie)$$

Zgodnie ze wzorem (87) tworzymy jednostkowy wektor barycentryczny  $\mathbf{p}_{ICRF}$  gwiazdy

$$\mathbf{p}_{ICRF} = \begin{pmatrix} 0.343\ 903\ 641 \\ 0.894\ 973\ 257 \\ 0.284\ 170\ 996 \end{pmatrix}$$

oraz, wykorzystując wzór (88) barycentryczny wektor  $\mathbf{m}_{ICRF}$  ruchu własnego gwiazdy

$$\mathbf{m}_{ICRF} = \begin{pmatrix} 0.000\ 076\ 255 \\ 0.000\ 283\ 297 \\ -0.000\ 009\ 261 \end{pmatrix}$$

Wyznaczamy parametr czasu  $t$

$$t = (JD(TCB) - 2\ 451\ 545.0)/36\ 525 = (2\ 459\ 225.021\ 9 - 2\ 451\ 545.000\ 0)/36\ 525 = 0.210\ 267\ 540$$

i korzystając ze wzoru (89) obliczamy wektor pozycji barycentrycznej  $\mathbf{p}_{BCRF}$  gwiazdy w  $BCRF$

$$\mathbf{p}_{BCRF} = \begin{pmatrix} 0.343\ 919\ 675 \\ 0.895\ 032\ 825 \\ 0.284\ 169\ 049 \end{pmatrix}$$

Z tablicy na str. 112 Rocznika wypisujemy współrzędne  $X_B^E$ ,  $Y_B^E$ ,  $Z_B^E$  barycentrycznego wektora pozycji Ziemi na okalające daty i dokonujemy interpolacji na moment  $TCB$

<sup>28)</sup> Przedstawiona zamiana czasów ma na celu zwrócenie uwagi na fakt, że poszczególne dane, wykorzystywane w obliczeniach są tablicowane w dziedzinie różnych skal czasowych. W praktyce, różnice wynikające z rozróżnienia tych skal nie mają jednak wpływu na wyniki końcowe. We wszystkich obliczeniach w tym przykładzie można więc posługiwać się wyłącznie czasem  $UTC$ .

obliczamy pierwsze i drugie różnice

|      | $X_B^E$      |         | $Y_B^E$     |          | $Z_B^E$     |
|------|--------------|---------|-------------|----------|-------------|
| I.10 | -337 703 419 |         | 855 054 238 |          | 370 781 658 |
|      | -16 442 562  |         | -5 508 397  |          | -2 386 852  |
| 11   | -354 145 981 | 107 828 | 849 545 841 | -264 238 | 368 394 806 |
|      | -16 334 734  |         | -5 772 635  |          | -2 501 406  |
| 12   | -370 480 715 |         | 843 773 206 |          | 365 893 400 |

a następnie obliczamy współczynnik interpolacyjny  $n$

|                     |                        |   |
|---------------------|------------------------|---|
| zadany moment $TCB$ | 2021.I.10 <sup>d</sup> | 12 <sup>h</sup> 31 <sup>m</sup> 30 <sup>s</sup> .8963 |
| epoka efemerydy     | 2021.I.11              | 0 00 00.0000  |
| różnica             |                        | -11 28 29.1037  |

wsp. interpolacyjny  $n = \text{różnica}/24^h = -0.478\,114\,626$  i za pomocą wzoru interpolacyjnego Stirlinga liczymy interpolowane na moment  $TCB$  współrzędne wektora  $\mathbf{E}_B$

$$\begin{aligned} X_B^E &= [-354\,145\,981 - \frac{1}{2} \cdot 0.478\,114\,626 \cdot (-16\,442\,562 - 16\,334\,734 - 107\,828 \cdot 0.478\,114\,626)] \times 10^{-9} \\ Y_B^E &= [849\,545\,841 - \frac{1}{2} \cdot 0.478\,114\,626 \cdot (-5\,508\,397 - 5\,772\,635 + 264\,238 \cdot 0.478\,114\,626)] \times 10^{-9} \\ Z_B^E &= [368\,394\,806 - \frac{1}{2} \cdot 0.478\,114\,626 \cdot (-2\,386\,852 - 2\,501\,406 + 114\,554 \cdot 0.478\,114\,626)] \times 10^{-9} \end{aligned}$$

$$\mathbf{E}_B = \begin{pmatrix} -0.346\,298\,004 \\ 0.852\,212\,453 \\ 0.369\,550\,287 \end{pmatrix}$$

Przejście od  $BCRF$  do  $GCRF$  dokonuje się przy użyciu wzoru (90), po zastosowaniu którego uzyskujemy

$$\mathbf{p}_{GCRF} = \begin{pmatrix} 0.343\,919\,759 \\ 0.895\,032\,618 \\ 0.284\,168\,959 \end{pmatrix}$$

Z tablicy na str. 112 Rocznika wypisujemy współrzędne  $X_H^E$ ,  $Y_H^E$ ,  $Z_H^E$  heliocentrycznego wektora pozycji Ziemi na okalające daty i dokonujemy interpolacji na moment  $TCB$  odpowiadający momentowi  $UT1$  przykładu

obliczamy pierwsze i drugie różnice

| różnica            |                        | -11 28 50.6460                                       |

wsp. interpolacyjny  $n = \frac{-11^h 28^m 50.6460^s}{24^h} = -0.478\,363\,958$  i za pomocą wzoru interpolacyjnego Stirlinga liczymy interpolowane na moment  $TT$  wartości  $X$  oraz  $Y$  składowych wektora jednostkowego  $CIP$

$$X = [2\,012\,350 - \frac{1}{2} \cdot 0.478\,363\,958 \cdot (562 + 606 - 44 \cdot 0.478\,363\,958)] \times 10^{-9}$$

$$Y = [2\,190 - \frac{1}{2} \cdot 0.478\,363\,958 \cdot (-65 + 54 - 119 \cdot 0.478\,363\,958)] \times 10^{-9}$$

Korzystając z wrorów (33) lub (86) oraz przyjmując średnią wartość parametru  $s$  dla roku 2021 podaną na str. 121 obliczamy wartości współczynników macierzy precesyjno–nutacyjnej  $Q$  (w obliczeniach wymagających dokładności nie lepszej niż 10 *mas* wpływ parametru  $s$  można zaniedbać przyjmując  $s = 0$ ).

$$X^2 = 0.000\,004\,048, \quad XY = 0.000\,000\,004, \quad Y^2 = 0.000\,000\,000, \quad a = 0.500\,000\,506, \quad s = -0.000\,000\,023$$

$$1 - aX^2 = 0.999\,997\,976, \quad aXY = 0.000\,000\,002, \quad 1 - aY^2 = 1.000\,000\,000, \quad 1 - a(X^2 + Y^2) = 0.999\,997\,976$$

$$sX = sY = saXY = 0.000\,000\,000, \quad s(1 - aX^2) = -0.000\,000\,023, \quad s(1 - aY^2) = -0.000\,000\,023$$

$$Q = \begin{pmatrix} 0.999\,997\,976 & -0.000\,000\,025 & 0.002\,012\,076 \\ 0.000\,000\,021 & 1.000\,000\,000 & 0.000\,002\,206 \\ -0.002\,012\,076 & -0.000\,002\,206 & 0.999\,997\,976 \end{pmatrix}$$

Stosując wzór (95) obliczamy pozycję gwiazdy w  $IRS_{\text{NIEBIESKI}}$

$$\mathbf{p}_{IRS} = \begin{pmatrix} 0.343\,254\,777 \\ 0.895\,006\,390 \\ 0.284\,850\,352 \end{pmatrix}$$

a następnie korzystając z (96) otrzymujemy pozycję pozorną  $\alpha_{app}^{CIO}$ ,  $\delta_{app}$  gwiazdy

$$\alpha_{app}^{CIO} = 4^h 36^m 04.098^s$$

$$\delta_{app} = +16^\circ 32' 59.65''$$

Miejsca pozorne odniesione do równika  $CIP$  oraz do  $CIO$  różnią się od miejsc pozornych odniesionych do równika FK5 i punktu równonocy wiosennej. Jeśli jednak dokona się transformacji wyrażonej obrotem wokół  $CIP$  o kąt odpowiadający różnicy między prawdziwym czasem gwiazdowym  $GST$  i Kątem Obrotu Ziemi ( $ERA$ ), to rozbieżność w miejscach pozornych zostanie zredukowana do nieznaczonej zaledwie wielkości, która wynika z użycia, różnych w obu wypadkach, miejsc średnich i ruchów własnych gwiazd oraz różnych modeli precesyjno–nutacyjnych (do obliczenia pozycji pozornych odniesionych do równika  $CIP$  oraz do  $CIO$  są stosowane dane z katalogu Hipparcos oraz model precesyjno–nutacyjny IAU2006, zaś do obliczenia pozycji pozornych odniesionych do równika FK5 i punktu równonocy wiosennej są używane dane z katalogu FK5 oraz model IAU1976/IAU1980).

### Przybliżony azymut Biegunowej (str. 146)<sup>29)</sup>

Tablica zawiera przybliżone wartości azymutu Biegunowej, zestawione według dwóch argumentów: kąta godzinnego  $t$  Biegunowej i szerokości geograficznej  $\varphi$ .

Dla wartości kąta godzinnego  $t$  odczytanych z kolumny po lewej stronie, wartości w tablicy wyznaczają azymut liczony w kierunku przeciwnym do ruchu wskazówek zegara od kierunku północy (rzeczywisty azymut jest więc dopełnieniem podanych wartości do 360°); dla wartości  $t$  odczytanych z kolumny po prawej stronie tablicy, azymut jest liczony zgodnie z ruchem wskazówek zegara (tablica zawiera rzeczywiste wartości azymutu).

<sup>29)</sup> Obliczony wg wzoru:  $\tan A = \frac{-\cos \delta \sin t}{\sin \delta \cos \varphi - \cos \delta \sin \varphi \cos t}$ .

### Przybliżona odległość zenitalna Biegunowej (str. 147)

Tablice służą do obliczania wartości pozornej odległości zenitalnej Polaris z dokładnością jednej minuty łuku według wzoru

$$z' = (90^\circ - \varphi) + \Delta z \quad (97)$$

Argumentem tablic jest kąt godzinny  $t$  Biegunowej. Odstępy argumentu są dobrane tak, aby następującym po sobie interwałom kąta godzinnego odpowiadały kolejne, zmieniające się skokami co 1 minutę łuku wielkości  $\Delta z$ . Tak więc znając kąt  $t$  wystarczy odszukać w tablicach interwał, w którym on się mieści i odczytać poprawkę  $\Delta z$  odpowiadającą temu interwałowi.

W poprawkach  $\Delta z$  uwzględniono refrakcję normalną dla  $\varphi = 52^\circ$ .

Odległość zenitalną Biegunowej można obliczać przy pomocy omawianych tabel z dokładnością jednej minuty łuku w co najmniej dwudziestostopniowym pasie ( $\varphi = 40^\circ \div 60^\circ$ ). Należy korzystać z tabeli, w której nagłówku znajduje się wartość deklinacji najbliższa deklinacji pozornej Polaris w zadanym momencie.

### Szerokość geograficzna z wysokości Biegunowej (str. 148)

Podstawą tablic odnoszących się do wyznaczania szerokości geograficznej  $\varphi$  z pomiaru wysokości  $h = 90^\circ - z$  Biegunowej, jest wzór

$$\varphi = h - p \cos t + \frac{1}{2} p^2 \sin^2 t \tan h \sin 1'' - \dots \quad (98)$$

w którym  $p = 90^\circ - \delta$  oznacza odległość biegunową a  $t$  kąt godzinny Biegunowej. Wzór ten można przedstawić w następującej postaci:

$$\begin{aligned} \varphi &= h + V_I + V_{II} \\ V_I &= -p \cos t + \frac{1}{2} p^2 \sin^2 t \sin 1'', \quad V_{II} = \frac{1}{2} p^2 \sin^2 t (\tan h - 1) \sin 1'' \end{aligned} \quad (99)$$

Wartości wyrazu  $V_I$ , w zależności od argumentów  $p$  oraz  $t$ , zawiera tablica główna, zaś wartości wyrazu  $V_{II}$  (oddzielnie dla  $h < 40^\circ$  i  $h > 40^\circ$ ), w zależności od  $h$  i  $t$ , zawierają tablice pomocnicze.

### Współczynniki do wzorów interpolacyjnych (str. 149)

Tablice zawierają wartości współczynników do wzorów interpolacyjnych Stirlinga, Bessela i Newtona. Odnośne wzory zostały umieszczone u dołu strony. Przy interpolowaniu do środka ( $n = 0.5$ ) szczególnie korzystne jest stosowanie wzoru Bessela.

### Refrakcja (str. 150÷151)

Tablica na str. 150 zawiera wartości refrakcji normalnej  $R_0$  według *Radau* oraz ekstynkcji  $E_0$ , w zależności od pozornej odległości zenitalnej  $z'$  gwiazd, w odstępach  $1^\circ$  dla  $z'$  od  $0^\circ$  do  $50^\circ$  i w odstępach  $20'$  dla  $z'$  od  $50^\circ$  do  $91^\circ$ .

Na str. 151 podane są wartości współczynników:

$A$  zależny od temperatury  $t$  w  $^\circ C$ ,

$B$  zależny od ciśnienia  $H$  w  $mm\ Hg$ ,

$\alpha$  zależny od pozornej odległości zenitalnej  $z'$ ,

$\beta$  zależny od  $R_1$ ,

$\gamma$  zależny od odległości zenitalnej  $z'$  i temperatury  $t$ .

W celu wyznaczenia refrakcji całkowitej stosuje się następujące wzory:

$$R_1 = R_0(1 + A\alpha\gamma) \quad (100)$$

$$R = R_1(1 + B\beta) \quad (101)$$

- 11) Dane: zaobserwowane odległości zenitalne  $z'$ , temperatura zewnętrzna  $t$  oraz ciśnienie atmosferyczne  $H$  (wskazanie barometru). Obliczyć wpływ refrakcji atmosferycznej  $R$  i znaleźć rzeczywistą odległość zenitalną  $z = z' + R$ .

### Sygnały czasu (str. 152)

Podano aktualne informacje o wybranych, europejskich i światowych radiostacjach nadających całodobowo sygnały czasu. Dane te zostały zaczerpnięte z *BIPM Annual Report on Time Activities, Vol. 13, 2018*, wydawanego corocznie przez Bureau International des Poids et Mesures, w Sèvres oraz stron internetowych wybranych stacji nadawczych.

Poprawki do momentów emisji sygnałów względem Czasu Uniwersalnego Koordynowanego *UTC* są z reguły zanedbywalne w porównaniu do błędów znajomości czasu propagacji fal radiowych.

W Polsce sygnały czasu są nadawane przez rozgłośnie Polskiego Radia z Głównego Urzędu Miar, który wysyła sygnały złożone z sześciu krótkich znaków fonicznych, następujących po sobie w odstępach sekundowych. Początek ostatniego znaku oznacza równą godzinę z dokładnością większą niż 1 ms.

Z sygnałów Polskiego Radia można korzystać przy wyznaczeniach azymutu astronomicznego metodą kąta godzinnego Polaris. Poprawki tych sygnałów względem czasu koordynowanego, a także poprawki propagacyjne na obszarze Polski, są przy tym zanedbywalne. Do momentu emisji należy jedynie wprowadzać wartości  $DUT1^{30)}$  i przy przejściach do czasu południka Greenwich pamiętać o różnicy między czasem uniwersalnym a czasem urzędowym

$$DUT1 = UT1 - UTC \quad (102)$$

Większość emitowanych sygnałów dokładnego czasu zawiera w sobie informację o wartości poprawki  $DUT1$ , wyrażonej w  $0.1^{31)}$ . Dodatnia wartość  $DUT1$  jest wskazywana przez wyróżnienie następujących po sobie  $n$  sygnałów sekundowych po sygnale oznaczającym pełną minutę. Ujemna wartość  $DUT1$  jest wskazywana przez  $n$  następujących po sobie, wyróżnionych sygnałów sekundowych, począwszy od dziewiętej sekundy po impulsie oznaczającym pełną minutę

$$DUT1 = n \times 0.1 \quad (103)$$

Impulsy sekundowe sygnalizujące wartość poprawki  $DUT1$  są wyróżniane np.: przez przedłużenie sygnału, podwojenie, lub zmianę jego tonu.

### Mapa deklinacji magnetycznej (str. 153)

Z mapy deklinacji magnetycznej na epokę 2021.5 można wyinterpolować przybliżoną wartość deklinacji magnetycznej dla dowolnego punktu na obszarze Polski. Aby otrzymać wartość deklinacji na inną epokę, należy ekstrapolować liniowo z uwzględnieniem podanej zmiany rocznej. Epoka, na którą dokonuje się ekstrapolacji nie powinna odbiegać bardziej niż 5 lat od epoki mapy deklinacji.

### Zestawienie gwiazdozbiorów (str. 154÷155)

Zestawienie gwiazdozbiorów podano w oparciu o Atlas Nieba Gwiazdzistego (J. Dobrzycki, A. Dobrzycki, PWN 1989).

<sup>30)</sup> Informacje o wartościach poprawek  $DUT1$  są publikowane w biuletynie D IERS (<ftp://hpiers.obspm.fr/eop-pc/bul/buld/>).

<sup>31)</sup> Niektóre stacje jak np. RWM i RBU kodują w sygnałach czasu dodatkową informację ( $dUT1$ ), pozwalającą na określenie różnicy czasu  $UT1 - UTC$  z dokładnością do  $0.02$ .

### Mapa nieba gwiazdzistego (str. 156÷159)

Mapę sporządzono na podstawie *Bright Star Catalogue, 5th Revised Edition*. Mapa obejmuje gwiazdy jaśniejsze od 5 wielkości gwiazdowej. Współrzędne gwiazd odnoszą się do epoki J2000.0. Gwiazdy zmienne zaznaczono kółkami, zaś gwiazdy podwójne kreską. Oznaczenia literowe oraz liczbowe gwiazd podano dla gwiazd jaśniejszych od 4 wielkości gwiazdowej oraz wszystkich gwiazd zmiennych i podwójnych. Granice gwiazdozbiorów podano na podstawie *Catalogue of Constellation Boundary Data*, (A.C. Davenhall i S.K. Leggett, 1990), będącego przeliczoną na epokę J2000.0 wersją *Delimitation Scientifique des Constellations*, (E. Delporte, 1930).

### Niektóre stałe, definicje, wzory astronomiczne i geodezyjne (str. 160÷165)

Dane zamieszczone w tym dziale zaczerpnięto z IERS Technical Note 21 (lipiec 1996) i Journal of Geodesy, Vol. 74, No 1 (2000), a także z IERS Technical Note 32 „*IERS Conventions 2003*”, IAU Bulletin 88 „*Resolutions of the XXIVth General Assembly*” oraz z Rezolucji XXVI ZG IAU (Praga, 2006), a także Rezolucji XXVII ZG IAU (Rio de Janeiro, 2009).
